August 6, 2004, 11.44 hs.

Abstract

Two Augmented Lagrangian algorithms for solving KKT systems are introduced. The algorithms differ in the way in which penalty parameters are updated. Possibly infeasible accumulation points are characterized. It is proved that feasible limit points that satisfy the Constant Positive Linear Dependence constraint qualification are KKT solutions. Boundedness of the penalty parameters is proved under suitable assumptions. Numerical experiments are presented.

Key words: Nonlinear programming, Augmented Lagrangian methods, KKT systems, numerical experiments.

1 Introduction

Let \( F : \mathbb{R}^n \to \mathbb{R}^n \), \( h : \mathbb{R}^n \to \mathbb{R}^m \), \( \ell, u \in \mathbb{R}^n \), \( \ell < u \), \( \Omega = \{ x \in \mathbb{R}^n \mid \ell \leq x \leq u \} \).

Assume that \( h \) admits continuous first derivatives on an open set that contains \( \Omega \) and denote

\[
\nabla h(x) = (\nabla h_1(x), \ldots, \nabla h_m(x)) = h'(x)^T \in \mathbb{R}^{n \times m}.
\]

Let \( \mathcal{P}_A \) denote the Euclidean projection operator on a closed and convex set \( A \). A point \( x \in \Omega \) is said to be a KKT point of the problem defined by \( F, h \) and \( \Omega \) if there exists \( \lambda \in \mathbb{R}^m \) such that

\[
\mathcal{P}_\Omega [x - F(x) - \nabla h(x)\lambda] - x = 0, \quad h(x) = 0.
\]
If $F = \nabla f$ for some $f : \mathbb{R}^n \rightarrow \mathbb{R}$, the equations (1) represent the KKT optimality conditions of the minimization problem

$$\text{Minimize } f(x) \text{ subject to } h(x) = 0, \ x \in \Omega.$$  

(2)

The KKT form (1) allows one to consider more general situations, as equilibrium problems, variational inequalities and some variations. See [21, 23, 26, 27] and references therein. The introduction of the Fischer-Burmeister function [23] made it possible to reduce KKT systems to suitable semismooth nonlinear systems of equations. See [29, 30, 31]. Many authors used the semismooth approach to obtain interesting algorithms for solving KKT systems. See [18, 19, 20, 36].

The most influential work on practical Augmented Lagrangian algorithms for minimization with equality constraints and bounds was the paper by Conn, Gould and Toint [11], on which the LANCELOT package [9] is based. Convergence of the algorithm presented in [11] was proved under the assumption that the gradients of the general constraints and the active bounds at any limit point are linearly independent. See, also, [10]. In the present paper we do not use this assumption at all. Firstly, we characterize the situations in which infeasible limit points might exist using weaker assumptions than the linear independence condition. Moreover, the fact that feasible limit points are KKT points will follow using the Constant Positive Linear Dependence (CPLD) condition [32], which has been recently proved to be a constraint qualification [1] and is far more general than the regularity condition and other popular constraint qualifications. We use regularity, following closely the development of [11], only for proving boundedness of the penalty parameters.

This paper is organized as follows. The two main algorithms are introduced in Section 2. In Section 3 we characterize the infeasible points that could be limit points of the algorithms. In Section 4 it is proved that, if the CPLD constraint qualification holds at a feasible limit point, then this point must be KKT. In Section 5 we prove boundedness of the penalty parameters. In Section 6 we present numerical experiments. Conclusions and lines for future research are given in Section 7.

Notation.

Throughout this work, $[v]_i$ is the $i$–th component of the vector $v$. We also denote $v_i = [v]_i$ if this does not lead to confusion.

We denote:

$$\mathbb{R}_+ = \{ t \in \mathbb{R} \mid t \geq 0 \},$$

$$\mathbb{R}_{++} = \{ t \in \mathbb{R} \mid t > 0 \},$$

$$\mathbb{N} = \{ 0, 1, 2, \ldots \},$$

$$\{ e_1, \ldots, e_n \} = \text{the canonical basis of } \mathbb{R}^n.$$
2 Model algorithms

From here on we assume that $F$ is continuous. Given $x \in \Omega$, $\lambda \in \mathbb{R}^m$, $\rho \in \mathbb{R}^+$ we define

$$G_1(x, \lambda, \rho) = F(x) + \sum_{i=1}^{m} \lambda_i \nabla h_i(x) + \rho \sum_{i=1}^{m} h_i(x) \nabla h_i(x).$$

For $\rho \in \mathbb{R}^+_{++}$ we define

$$G_2(x, \lambda, \rho) = F(x) + \sum_{i=1}^{m} \lambda_i \nabla h_i(x) + \sum_{i=1}^{m} \rho_i h_i(x) \nabla h_i(x).$$

If the KKT system is originated in a minimization problem, the mapping $F$ is the gradient of some $f : \mathbb{R}^n \to \mathbb{R}$. In this case we define, for $\rho \in \mathbb{R}^+_{++}$,

$$L_1(x, \lambda, \rho) = f(x) + \sum_{i=1}^{m} \lambda_i h_i(x) + \frac{\rho}{2} \sum_{i=1}^{m} h_i(x)^2$$

and, for $\rho \in \mathbb{R}^+_{++}$,

$$L_2(x, \lambda, \rho) = f(x) + \sum_{i=1}^{m} \lambda_i h_i(x) + \frac{1}{2} \sum_{i=1}^{m} \rho_i h_i(x)^2.$$

In these cases we have that $\nabla L_1 = G_1$ and $\nabla L_2 = G_2$. The functions $L_1$ and $L_2$ are one-parameter and many-parameters Augmented Lagrangians associated to the problem (2).

The mappings $G_1$ and $G_2$ will be used to define one-parameter and many-parameters Augmented Lagrangian algorithms for solving the general KKT problem (1). These algorithms are described below.

Algorithm 1.

Let $x_0 \in \Omega$, $\tau \in [0, 1)$, $\gamma > 1$, $-\infty < \bar{\lambda}_{\min} < \bar{\lambda}_{\max} < \infty$, $\rho_1 > 0$, $\bar{\lambda}_1 \in [\bar{\lambda}_{\min}, \bar{\lambda}_{\max}]^m$. Let $\{\varepsilon_k\}_{k \in \mathbb{N}} \subset \mathbb{R}^+_+$ be a sequence that converges to zero.

Step 1. Initialization
Set $k \leftarrow 1$.

Step 2. Solving the subproblem
Compute $x_k \in \Omega$ such that

$$\|P_\Omega[x_k - G_1(x_k, \bar{\lambda}_k, \rho_k)] - x_k\|_\infty \leq \varepsilon_k. \quad (3)$$

Step 3. Estimate multipliers
Define for all $i = 1, \ldots, m$,

$$[\lambda_{k+1}]_i = [\bar{\lambda}_k]_i + \rho_i h_i(x_k). \quad (4)$$

If $h(x_k) = 0$ and $P_\Omega[x_k - G_1(x_k, \bar{\lambda}_k, \rho_k)] - x_k = 0$ terminate the execution of the algorithm. (In this case, $x_k$ is a KKT point and $\lambda_{k+1}$ is the associated vector of Lagrange multipliers.)
Compute
\[ \lambda_{k+1} \in [\lambda_{\text{min}}, \lambda_{\text{max}}]^m. \] (5)

**Step 4. Update the penalty parameter**

If
\[ \| h(x_k) \|_\infty \leq \tau \| h(x_{k-1}) \|_\infty \]
define
\[ \rho_{k+1} = \rho_k, \]
else, define
\[ \rho_{k+1} = \gamma \rho_k. \]

**Step 5. Begin a new iteration**

Set \( k \leftarrow k + 1 \). Go to Step 2.

Algorithm 2 only differs from Algorithm 1 in the way in which penalty parameters are updated. In Algorithm 2 we use one penalty parameter for each constraint.

**Algorithm 2.**

Let \( x_0 \in \Omega, \tau \in [0,1), \gamma > 1, -\infty < \lambda_{\text{min}} < \lambda_{\text{max}} < \infty, \rho_1 \in \mathbb{R}^m_{++}, \lambda_1 \in [\lambda_{\text{min}}, \lambda_{\text{max}}]^m \). Let \( \{\varepsilon_k\}_{k \in \mathbb{N}} \subset \mathbb{R}_{++} \) be a sequence that converges to zero.

**Step 1. Initialization**

Set \( k \leftarrow 1 \).

**Step 2. Solving the subproblem**

Compute \( x_k \in \Omega \) such that
\[ \| P_\Omega [x_k - G_2(x_k, \lambda_k, \rho_k)] - x_k \|_\infty \leq \varepsilon_k. \] (7)

**Step 3. Estimate multipliers**

Define for all \( i = 1, \ldots, m, \)
\[ [\lambda_{k+1}]_i = [\lambda_k]_i + [\rho_k]_i h_i(x_k) \] (8)

If \( h(x_k) = 0 \) and \( P_\Omega [x_k - G_2(x_k, \lambda_k, \rho_k)] - x_k = 0 \) terminate the execution of the algorithm.

(As in Algorithm 1, \( x_k \) is a KKT point and \( \lambda_{k+1} \) is the vector of Lagrange multipliers.)

Compute
\[ \lambda_{k+1} \in [\lambda_{\text{min}}, \lambda_{\text{max}}]^m. \] (9)

**Step 4. Update the penalty parameters**

For all \( i = 1, \ldots, m, \) if
\[ |h_i(x_k)| \leq \tau \| h(x_{k-1}) \|_\infty \]
define
\[ [\rho_{k+1}]_i = [\rho_k]_i. \]
Else, define \[ [\rho_{k+1}]_{i} = \gamma |\rho_k|_{i}. \]

**Step 5.** Begin a new iteration
Set \( k \leftarrow k + 1 \). Go to Step 2.

**Remarks.**

1. The difference between Algorithms 1 and 2 relies on the updating formula for the penalty parameters. In the case in which Algorithm 2 updates at least one penalty parameter, Algorithm 1 updates its unique penalty parameter. In such a situation, other penalty parameters may remain unchanged in Algorithm 2. Therefore, the penalty parameters at Algorithm 2 tend to be smaller than the penalty parameter at Algorithm 1.

2. The global convergence results to be presented in the following sections are independent of the choice of \( \lambda_{k+1} \) in (5) and (9).

3. The Augmented Lagrangian algorithms are based on the resolution of the inner problems (3) and (7). In the minimization case \( F = \nabla f \) the most reasonable way for obtaining these conditions is to solve (approximately) the box-constrained minimization problem

\[
\text{Minimize } L_1(x, \lambda_k, \rho_k) \text{ subject to } x \in \Omega \tag{10}
\]

in the case of Algorithm 1, and

\[
\text{Minimize } L_2(x, \lambda_k, \rho_k) \text{ subject to } x \in \Omega \tag{11}
\]

in the case of Algorithm 2. Both (10) and (11) are box-constrained minimization problems. Since \( \Omega \) is compact, minimizers exist and stationary points can be obtained up to any arbitrary precision using reasonable algorithms. Sufficient conditions under which points that satisfy (3) and (7) exist and can be obtained by available algorithms in more general problems have been analyzed in many recent papers. See [18, 19, 20, 21, 26].

3 Convergence to feasible points

At a KKT point we have that \( h(x) = 0 \) and \( x \in \Omega \). Points that satisfy these two conditions are called feasible. It would be nice to have algorithms that find feasible points in every situation, but this is impossible. (In an extreme case, feasible points might not exist at all.) Therefore, it is important to study the behavior of algorithms with respect to infeasibility.

Briefly speaking, in this section we show that Algorithm 1 always converges to stationary points of the problem of minimizing \( \|h(x)\|_2^2 \) subject to \( \ell \leq x \leq u \). In the case of Algorithm 2 we will show that the set of possible limit points must be solutions of a weighted least-squares problem involving the constraints.

In the proof of both theorems we will use the following obvious property:

\[
\|P_\Omega(u + tv) - u\|_2 \leq \|P_\Omega(u + v) - u\|_2 \quad \forall u \in \Omega, v \in \mathbb{R}^n, t \in [0, 1]. \tag{12}
\]
**Theorem 3.1.** Assume that the sequence \( \{x_k\} \) is generated by Algorithm 1 and that \( x_* \) is a limit point. Then, \( x_* \) is a stationary point of the problem

\[
\begin{align*}
\text{Minimize } & \|h(x)\|^2_2 \\
\text{subject to } & x \in \Omega.
\end{align*}
\] (13)

**Proof.** Let \( K \subset \mathbb{N} \) be such that \( \lim_{k \to K} x_k = x_* \).

By (3) and the equivalence of norms in \( \mathbb{R}^n \), we have that

\[
\lim_{k \to \infty} \left\| \mathcal{P}_\Omega[x_k - F(x_k) - \sum_{i=1}^{m} \left( \frac{\lambda_k^i}{\rho_k} + \rho_k h_i(x_k) \right) \nabla h_i(x_k) \right\|_2 = 0. \quad (14)
\]

By (6), if \( \{\rho_k\}_{k \in K} \) is bounded we have that \( h(x_*) = 0 \), so \( x_* \) is a stationary point of (13).

Assume that \( \{\rho_k\}_{k \in K} \) is unbounded. Since \( \{\rho_k\} \) is nondecreasing, we have that

\[
\lim_{k \to \infty} \rho_k = \infty. \quad (15)
\]

Then, \( \rho_k > 1 \) for \( k \in K \) large enough. So, using (12) with

\[
u = x_k, \quad v = -F(x_k) - \sum_{i=1}^{m} \left( \frac{\lambda_k^i}{\rho_k} + \rho_k h_i(x_k) \right) \nabla h_i(x_k), \quad t = 1/\rho_k,
\]

we have, by (14), that

\[
\lim_{k \to \infty} \left\| \mathcal{P}_\Omega \left[ x_k - \frac{F(x_k)}{\rho_k} - \sum_{i=1}^{m} \left( \frac{\lambda_k^i}{\rho_k} + \rho_k h_i(x_k) \right) \nabla h_i(x_k) \right] - x_k \right\|_2 = 0. \quad (16)
\]

By (15) and (16), since \( \{\lambda_k\}_{k \in K} \) is bounded, we obtain:

\[
\| \mathcal{P}_\Omega[x_* - \sum_{i=1}^{m} h_i(x_*) \nabla h_i(x_*)] - x_* \|_2 = 0.
\]

This means that \( x_* \) is a stationary point of (13), as we wanted to prove. \( \quad \square \)

We say that an infeasible point \( x_* \in \Omega \) is *degenerate* if there exists \( w \in \mathbb{R}^n \) such that \( x_* \) is a stationary point of the weighted least-squares problem

\[
\begin{align*}
\text{Minimize } & \sum_{i=1}^{m} w_i h_i(x)^2 \\
\text{subject to } & x \in \Omega,
\end{align*}
\] (17)

and

\[
\sum_{i=1}^{m} w_i h_i(x_*)^2 > 0. \quad (18)
\]

**Theorem 3.2.** Let \( \{x_k\} \) be a sequence generated by Algorithm 2. Then, at least one of the following possibilities hold:

6
1. The sequence admits a feasible limit point.

2. The sequence admits an infeasible degenerate limit point.

Proof. Assume that all the limit points of the sequence \( \{x_k\} \) are infeasible. Therefore, there exists \( \varepsilon > 0 \) such that

\[
\|h(x_k)\|_\infty \geq \varepsilon
\]

for all \( k \in \mathbb{N} \). This implies that

\[
\lim_{k \to \infty} \|\rho_k\|_\infty = \infty.
\]

Let \( K \) be an infinite subset of \( \mathbb{N} \) such that

\[
\|\rho_k\|_\infty > \|\rho_{k-1}\|_\infty \quad \forall \ k \in K.
\]

Let \( K_1 \) be an infinite subset of \( K \) and \( j \in \{1, \ldots, m\} \) be such that

\[
\|\rho_k\|_\infty = [\rho_k]_j \quad \forall \ k \in K_1.
\]

Then, by (20),

\[
[\rho_k]_j = \gamma [\rho_{k-1}]_j \quad \forall \ k \in K_1.
\]

By the definition of the algorithm, we have that, for all \( k \in K_1 \),

\[
|h_j(x_{k-1})| > \tau \|h(x_{k-2})\|_\infty.
\]

So, by (19),

\[
|h_j(x_{k-1})| > \tau \varepsilon \quad \forall \ k \in K_1.
\]

Moreover, by the definition of the algorithm, (20) and (21), we have:

\[
[\rho_{k-1}]_j \geq \frac{\|\rho_{k-1}\|_\infty}{\gamma} \forall \ k \in K_1.
\]

Let \( K_2 \) be an infinite subset of indices of \( \{k - 1\}_{k \in K_1} \) such that

\[
\lim_{k \to K_2} x_k = x_*.
\]

By (22) we have that

\[
h_j(x_*) \neq 0.
\]

By (7) and the equivalence of norms in \( \mathbb{R}^n \), we have:

\[
\lim_{k \to \infty} \|P_\Omega[x_k - F(x_k) - \sum_{i=1}^m ([\lambda_k]_i + [\rho_k]_i h_i(x_k)) \nabla h_i(x_k)] - x_k\|_2 = 0.
\]

Clearly \( \|\rho_k\|_\infty > 1 \) for \( k \in K_2 \) large enough. So, using (12) with

\[
u = x_k, \; v = -F(x_k) - \sum_{i=1}^m ([\lambda_k]_i + [\rho_k]_i h_i(x_k)) \nabla h_i(x_k), \; t = 1/\|\rho_k\|_\infty,
\]

7
we have, by (25), that
\[
\lim_{k \in K_2} \left\| P_{\Omega} \left[ x_k - \frac{F(x_k)}{\| \rho_k \|_\infty} - \frac{1}{m} \sum_{i=1}^{m} \left( \frac{\lambda_k}{\| \rho_k \|_\infty} + \frac{[\rho_k]_i}{\| \rho_k \|_\infty} \right) \nabla h_i(x_k) \right] - x_k \right\|_2 = 0. \tag{26}
\]
But
\[
\frac{[\rho_k]_i}{\| \rho_k \|_\infty} \leq 1 \quad \forall i = 1, \ldots, m.
\]
Therefore, there exist \( K_3 \subset K_2 \) and \( w \in H_{+}^m \) such that
\[
\lim_{k \in K_1} \frac{[\rho_k]_i}{\| \rho_k \|_\infty} = w_i \quad \forall i = 1, \ldots, m.
\]
Moreover, by (23),
\[
w_j > 0. \tag{27}
\]
Since \( \{ \lambda_k \}_{k \in K_1} \) is bounded, taking limits for \( k \in K_1 \) in (26), we get:
\[
\| P_{\Omega} [x_* - \sum_{i=1}^{m} w_i h_i(x_*) \nabla h_i(x_*)] - x_* \|_2 = 0.
\]
So, \( x_* \) is a stationary point of (17). By (24) and (27), the condition (18) also takes place. Therefore, \( x_* \) is a degenerate infeasible point.

\[\square\]

**Remark.** Clearly, any infeasible stationary point of (13) must be degenerate. Moreover, if \( x \) is infeasible and degenerate, by (18) and the KKT conditions of (17), the gradients of the equality constraints and the active bound constraints are linearly dependent. The reciprocal is not true. In fact, consider the set of constraints
\[
h(x) = x = 0 \in \mathbb{R}^1, \quad -1 \leq x \leq 1. \tag{28}
\]
At the points \( z = -1 \) and \( z = 1 \) the gradients of equality constraints and active bound constraints are linearly dependent but these points are not degenerate. In [11] it is assumed that, at all the limit points of the sequence generated by the Augmented Lagrangian algorithm, the gradients of equality constraints and active bound constraints are linearly independent (Assumption AS3 of [11]). See also, [10]. Under this assumption it is proved that the limit points are feasible. By the considerations above, we see that Assumption AS3 is stronger than assuming the nonexistence of infeasible degenerate points. In other words, the assumption on the problem that guarantees that AS3 holds is that the gradients of equality constraints and active bound constraints are linearly independent at all the points of the box (not merely at the feasible points). This assumption does not hold in (28) and is much stronger than assuming that there are no degenerate points in \( \Omega \).
4 Convergence to optimal points

In this section we investigate under which conditions a feasible limit point of a sequence generated by the Augmented Lagrangian algorithms is a KKT point. The main result is that a feasible limit point is KKT if it satisfies the Constant Positive Linear Dependence condition (CPLD). The CPLD condition was introduced by Qi and Wei in [32]. More recently [1], it was proved that this condition is a constraint qualification. A feasible point satisfies CPLD if one of the following situations take place:

1. The point satisfies the Mangasarian-Fromovitz constraint qualification [28, 35].
2. The point does not satisfy the Mangasarian-Fromovitz constraint qualification but any set of positive linear dependent gradients of active constraints (including equality constraints) remains linearly dependent in a neighborhood of the point.

Obviously, the CPLD condition is weaker than the Mangasarian-Fromovitz constraint qualification. The AS3 condition of [11], when applied only to feasible points, is the classical regularity assumption (linear independence of the gradients of active constraints). In [1] examples where the CPLD condition holds but the Mangasarian-Fromovitz condition does not were given. Of course, at points that do not satisfy Mangasarian-Fromovitz the gradients of active constraints are linearly dependent. Therefore, convergence results based on the CPLD condition are stronger than convergence results that assume the classical regularity condition.

Theorem 4.1. Assume that \( \{x_k\} \) is a sequence generated by Algorithm 1 or by Algorithm 2 and that \( x_* \) is a feasible limit point that satisfies the CPLD constraint qualification. Then, \( x_* \) is a KKT point.

Proof. Let us write, for Algorithm 1,

\[
G^k = G_1(x_k, \bar{\lambda}_k, \rho_k)
\]

and, for Algorithm 2,

\[
G^k = G_2(x_k, \bar{\lambda}_k, \rho_k).
\]

Define, for all \( k \in \mathbb{N} \),

\[
v_k = P_\Omega(x_k - G^k).
\]

Therefore, \( v_k \in \mathbb{R}^n \) solves

Minimize \( \|v - (x_k - G^k)\|_2^2 \)

subject to \( \ell \leq v \leq u \).

By the KKT conditions of this problem, there exist \( \mu^{u}_k \in \mathbb{R}^m_{++}, \mu^{l}_k \in \mathbb{R}^m_{++} \) such that, for all \( k \in \mathbb{N} \),

\[
v_k - x_k + G^k + \sum_{i=1}^{n} \mu^{u}_k e_i - \sum_{i=1}^{n} \mu^{l}_k e_i = 0
\] (29)
and

\[ [\mu^u_k]_i (u_i - [x_k]_i) = [\mu^l_k]_i (l_i - [x_k]_i) = 0 \quad \forall \quad i = 1, \ldots, n. \quad (30) \]

By (3) and (7),

\[ \lim_{k \to \infty} v_k - x_k = 0, \]

then, by (29),

\[ \lim_{k \to \infty} G^k + \sum_{i=1}^n [\mu^u_k]_i e_i - \sum_{i=1}^n [\mu^l_k]_i e_i = 0. \]

So, defining \( \lambda_{k+1} \) as in (4) and (8),

\[ \lim_{k \to \infty} F(x_k) + \nabla h(x_k) \lambda_{k+1} + \sum_{i=1}^n [\mu^u_k]_i e_i - \sum_{i=1}^n [\mu^l_k]_i e_i = 0. \quad (31) \]

Assume now that \( K \) is an infinite subset of \( \mathbb{N} \) such that

\[ \lim_{k \to \infty} x_k = x_* \quad (32) \]

Define:

\[ I_L = \{ i \in \{1, \ldots, n\} \mid [x_*]_i = l_i \}, \]

\[ I_U = \{ i \in \{1, \ldots, n\} \mid [x_*]_i = u_i \}, \]

\[ I_0 = \{ i \in \{1, \ldots, n\} \mid l_i < [x_*]_i < u_i \}. \]

By (32), there exists \( k_0 \in \mathbb{N} \) such that for all \( k \in K, k \geq k_0, \)

\[ i \in I_0 \Rightarrow l_i < [x_k]_i < u_i. \]

So, by (30), for all \( k \in K, k \geq k_0, \) we have:

\[ [\mu^u_k]_i = 0 \forall \ i \notin I_U \]

and

\[ [\mu^l_k]_i = 0 \forall \ i \notin I_L. \]

So, by (31),

\[ \lim_{k \to \infty} F(x_k) + \nabla h(x_k) \lambda_{k+1} + \sum_{i \in I_U} [\mu^u_k]_i e_i - \sum_{i \in I_L} [\mu^l_k]_i e_i = 0. \]

Define, for \( k \in K, k \geq k_0, \)

\[ E_k = F(x_k) + \nabla h(x_k) \lambda_{k+1} + \sum_{i \in I_U} [\mu^u_k]_i e_i - \sum_{i \in I_L} [\mu^l_k]_i e_i. \]

Clearly,

\[ \lim_{k \to \infty} E_k = 0 \]

10
and
\[ E_k - F(x_k) = \nabla h(x_k) \lambda_{k+1} + \sum_{i \in \tilde{I}_u} [\tilde{\mu}_k^u]_i e_i - \sum_{i \in \tilde{I}_l} [\tilde{\mu}_k^l]_i e_i \]  

(33)

for all \( k \in K, k \geq k_0 \).

By Caratheodory’s Theorem of Cones (see [2], page 689), for all \( k \in K, k \geq k_0 \) there exist
\[ \tilde{I}_k \subset \{1, \ldots, m\}, \tilde{I}_{uk} \subset I_u, \tilde{I}_{lk} \subset I_l, \]

\[ [\lambda_k]_i \forall i \in \tilde{I}_k, \ [\tilde{\mu}_k^u]_i \geq 0 \forall i \in \tilde{I}_{uk}, \ [\tilde{\mu}_k^l]_i \geq 0 \forall i \in \tilde{I}_{lk} \]
such that the vectors
\[ \{\nabla h_i(x_k)\}_{i \in \tilde{I}_k}, \ {e_i}_{i \in \tilde{I}_{uk}}, \ {-e_i}_{i \in \tilde{I}_{lk}} \]
are linearly independent and
\[ E_k - F(x_k) = \sum_{i \in \tilde{I}_k} [\lambda_k]_i \nabla h_i(x_k) + \sum_{i \in \tilde{I}_{uk}} [\tilde{\mu}_k^u]_i e_i - \sum_{i \in \tilde{I}_{lk}} [\tilde{\mu}_k^l]_i e_i. \]  

(34)

Since there is only a finite number of possible sets \( \tilde{I}_k, \tilde{I}_{uk}, \tilde{I}_{lk}, \) there exists an infinite set of indices
\[ K_1 \subset \{ k \in K \mid k \geq k_0 \} \]
such that
\[ \tilde{I}_k = I, \tilde{I}_{uk} = I_u, \tilde{I}_{lk} = I_l \]
for all \( k \in K_1 \).

Therefore, by (34),
\[ E_k - F(x_k) = \sum_{i \in I} [\lambda_k]_i \nabla h_i(x_k) + \sum_{i \in I_u} [\tilde{\mu}_k^u]_i e_i - \sum_{i \in I_l} [\tilde{\mu}_k^l]_i e_i \]  

(35)

and the vectors
\[ \{\nabla h_i(x_k)\}_{i \in I}, \ {e_i}_{i \in I_u}, \ {-e_i}_{i \in I_l} \]
are linearly independent

(36)

for all \( k \in K_1 \).

Define
\[ S_k = \max\{\max\{[\lambda_k]_i, i \in I\}, \max\{[\tilde{\mu}_k^u]_i, i \in I_u\}, \max\{[\tilde{\mu}_k^l]_i, i \in I_l\}\}. \]

We consider two possibilities:

- \( \{S_k\}_{k \in K_1} \) bounded;
- \( \{S_k\}_{k \in K_1} \) unbounded.
In the first case there exists $K_2$, an infinite subset of $K_1$, such that
\[
\lim_{k \in K_2} [\lambda_k]_i = \lambda_i,
\]
\[
\lim_{k \in K_2} [\mu_k^u]_i = \mu^u_i \geq 0 \forall i \in \tilde{I}_u
\]
and
\[
\lim_{k \in K_2} [\mu_k^l]_i = \mu^l_i \geq 0 \forall i \in \tilde{I}_l.
\]
So, taking limits in (35) for $k \in K_2$ we obtain that $x_*$ is a KKT point.

Suppose now that $\{S_k\}_{k \in K_1}$ is unbounded. Let $K_3$ be an infinite subset of $K_1$ such that $\lim_{k \in K_3} S_k = \infty$ and $S_k > 1$ for all $k \in K_3$. Dividing both sides of (35) by $S_k$ for all $k \in K_3$, we get:
\[
\frac{E_k - F(x_k)}{S_k} = \sum_{i \in I} [\lambda_k]_i \nabla h_i(x_k) + \sum_{i \in I_u} [\mu_k^u]_i e_i - \sum_{i \in I_l} [\mu_k^l]_i e_i.
\] (37)

By the definition of $S_k$, this quantity is the modulus of one of the coefficients $[\lambda_k]_i, [\mu_k^u]_i, [\mu_k^l]_i$ that occur in (37). Therefore, we can extract an infinite set $K_4 \subset K_3$ such that, for all $k \in K_4$, $S_k$ is the modulus of the same coefficient. But, since
\[
\left| \frac{[\lambda_k]_i}{S_k} \right| \leq 1, \left| \frac{[\mu_k^u]_i}{S_k} \right| \leq 1, \left| \frac{[\mu_k^l]_i}{S_k} \right| \leq 1,
\]
there exists $K_5$, an infinite subset of $K_4$, such that
\[
\lim_{k \in K_5} [\lambda_k]_i = \lambda_i, \lim_{k \in K_5} [\mu_k^u]_i = \mu^u_i \geq 0, \lim_{k \in K_5} [\mu_k^l]_i = \mu^l_i \geq 0.
\]

Then, taking limits on both sides of (37) for $k \in K_5$ we obtain that
\[
\sum_{i \in I} \lambda_i \nabla h_i(x_*) + \sum_{i \in I_u} \mu^u_i e_i - \sum_{i \in I_l} \mu^l_i e_i = 0.
\]
Moreover, by the choice of $K_4$, the modulus of at least one of the coefficients $\lambda_i, \mu^u_i, \mu^l_i$ is equal to 1. Therefore, the gradients
\[
\{\nabla h_i(x_*)\}_{i \in I}, \{e_i\}_{i \in I_u}, \{-e_i\}_{i \in I_l}
\]
are positively linearly dependent. By the CPLD condition the gradients
\[
\{\nabla h_i(x)\}_{i \in I}, \{e_i\}_{i \in I_u}, \{-e_i\}_{i \in I_l}
\]
must be linear dependent in a neighborhood of $x_*$. This contradicts (36). So, the theorem is proved. \[\Box\]
5 Boundedness of the penalty parameters

In this section we assume that the sequence \( \{x_k\} \), generated by Algorithm 1 or by Algorithm 2, converges to a KKT point \( x_* \in \Omega \). To simplify the arguments, as in [11], we assume without loss of generality that \( [x_*]_i < u_i \) for all \( i = 1, \ldots, n \) and that \( \ell_i = 0 \) for all \( i = 1, \ldots, n \). The Lagrange multipliers associated to \( x_* \) will be denoted \( \lambda_* \in \mathbb{R}^m \).

We will assume that \( F'(x) \) and \( \nabla^2 h_i(x) \) exist and are Lipschitz-continuous for all \( x \in \Omega \).

Finally, we will also make use of the following Nonsingularity Assumption:

**Assumption NS Define**

\[
J_1 = \{ i \in \{1, \ldots, n\} \mid [F(x_*) + \sum_{j=1}^m [\lambda_*]_j \nabla h_j(x_*)]_i = 0 \text{ and } [x_*]_i > 0 \}
\]

\[
J_2 = \{ i \in \{1, \ldots, n\} \mid [F(x_*) + \sum_{j=1}^m [\lambda_*]_j \nabla h_j(x_*)]_i = 0 \text{ and } [x_*]_i = 0 \}.
\]

Then, the matrix

\[
\begin{pmatrix}
[F'(x_*) + \sum_{j=1}^m [\lambda_*]_j \nabla h_j(x_*)]_{[l,j]} & (h'(x_*)_{[j]})^T \\
h'(x_*)_{[j]} & 0
\end{pmatrix}
\]

is nonsingular for all \( J = J_1 \cup K \) such that \( K \subset J_2 \).

Assumption NS, which corresponds to Assumption AS5 of [11], will be supposed to be true all along the section. Moreover, we will also assume that the computation of \( \overline{\lambda}_k \) at Step 2 of both algorithms is:

\[
[\overline{\lambda}_k]_i = \max\{\overline{\lambda}_{\min}, \min\{\overline{\lambda}_{\max}, \{[\lambda_k]_i\}\}\}
\]

for all \( i = 1, \ldots, m \).

Finally, we will assume that the true Lagrange multipliers \( [\lambda_*]_i \) satisfy

\[
[\overline{\lambda}_{\min}]_i < [\lambda_*]_i < [\overline{\lambda}_{\max}]_i \quad \forall \quad i = 1, \ldots, m.
\]

**Lemma 5.1.** Assume that the sequence \( \{x_k\} \) is generated by Algorithm 1 and that, for all \( k \in \mathbb{N} \),

\[
\lambda_{k+1} = \overline{\lambda}_k + \rho_k h(x_k).
\]

Then, there exist \( k_0 \in \mathbb{N}, \rho, a_1, a_2, a_3, a_4, a_5, a_6 > 0 \) such that, for all \( k \geq k_0 \),

\[
\|\lambda_{k+1} - \lambda_*\|_\infty \leq a_1 \varepsilon_k + a_2 \|x_k - x_*\|_\infty.
\]

Moreover, if \( \rho_{k_0} \geq \rho \), we have:

\[
\|x_k - x_*\|_\infty \leq a_3 \varepsilon_k + a_4 \frac{\|\overline{\lambda}_k - \lambda_*\|_\infty}{\rho_k},
\]

\[13\]
\[
\| \lambda_{k+1} - \lambda_* \|_\infty \leq a_5 \varepsilon_k + a_6 \frac{\| \tilde{\lambda}_k - \lambda_* \|_\infty}{\rho_k}
\]
(40)

and

\[
\| h(x_k) \|_\infty \leq a_5 \varepsilon_k \frac{1}{\rho_k} + (1 + \frac{a_6}{\rho_k}) \frac{\| \tilde{\lambda}_k - \lambda_* \|_\infty}{\rho_k}.
\]
(41)

Proof. The proof is identical to the ones of Lemmas 4.3 and 5.1 of [11], replacing \( \mu_k \) by \( 1/\rho_k \) and using the equivalence of norms in \( \Re^n \). \qed

Lemma 5.2. Assume that the sequence \( \{x_k\} \) is generated by Algorithm 1. Then, there exists \( k_0 \in \mathbb{N} \) such that for all \( k \geq k_0 \),

\[
\tilde{\lambda}_k = \lambda_k.
\]

Proof. By (39) there exists \( k_1 \in \mathbb{N} \) such that

\[
\| \lambda_{k+1} - \lambda_* \|_\infty \leq a_1 \varepsilon_k + a_2 \| x_k - x_* \|_\infty \quad \text{for all } k \geq k_1.
\]
(42)

Define \( \epsilon = \frac{1}{2} \min \{ |\lambda_k| - \tilde{\lambda}_{\min}, \tilde{\lambda}_{\max} - |\lambda_*| \} > 0 \). Since \( \| x_k - x_* \|_\infty \to 0 \) and \( \varepsilon_k \to 0 \), by (42) we obtain that there exists \( k_0 \geq k_1 \) such that

\[
\| \lambda_{k+1} - \lambda_* \|_\infty \leq \epsilon \quad \text{for all } k \geq k_0.
\]

By the definition of \( \epsilon \) we obtain the desired result. \qed

Theorem 5.1 Assume that the sequence \( \{x_k\} \) is generated by Algorithm 1 and that \( \varepsilon_k \) is such that

\[
\varepsilon_k = \min \{ \varepsilon'_k, \| h(x_k) \|_\infty \}
\]
(43)

where \( \{ \varepsilon'_k \} \) is a decreasing sequence that tends to zero. Then, the sequence of penalty parameters \( \{ \rho_k \} \) is bounded.

Proof. Let \( k_0 \) be as in Lemma 5.2. Then, for all \( k \geq k_0 \), we have that \( \tilde{\lambda}_k = \lambda_k \).

Assume that \( \rho_k \to \infty \). By (41) and (43) there exists \( k_1 \geq k_0 \) such that

\[
\| h(x_k) \|_\infty \leq (1 + \frac{a_6}{\rho_k})(\frac{1}{1 - \frac{a_5}{\rho_k}}) \frac{\| \lambda_k - \lambda_* \|_\infty}{\rho_k} \quad \text{for all } k \geq k_1
\]
(44)

whenever \( \frac{a_5}{\rho_k} < 1 \).

Since \( \tilde{\lambda}_k = \lambda_{k-1} + \rho_{k-1} h(x_{k-1}) \) we get

\[
\| h(x_{k-1}) \|_\infty = \frac{\| \lambda_k - \lambda_{k-1} \|_\infty}{\rho_{k-1}} \geq \frac{\| \lambda_{k-1} - \lambda_* \|_\infty}{\rho_{k-1}} - \frac{\| \lambda_k - \lambda_* \|_\infty}{\rho_{k-1}}.
\]

Then, by (40) and (43),

\[
\| \lambda_k - \lambda_* \|_\infty \leq \frac{1}{a_6 - \frac{a_6}{\rho_{k-1}}} (1 + \frac{a_5}{\rho_{k-1}} \| h(x_{k-1}) \|_\infty).
\]
(45)
Replacing (45) in (44) we obtain:

$$
\| h(x_k) \|_\infty \leq m_k \| h(x_{k-1}) \|_\infty
$$

whenever

$$
m_k = \frac{\bar{m}}{\rho_k},
$$

where $\bar{m}$ is a positive constant.

Since $\lim_{k \to \infty} m_k = 0$, there exists $k_2 \geq k_1$ such that $m_k < \tau$ and $\rho_{k+1} = \rho_k$ for all $k \geq k_2$. This is a contradiction. \hfill  \Box

From now on, if the sequence $\{x_k\}$ is generated by Algorithm 2, we define

$$
I_\infty = \{ i \in \{1, \ldots, m\} \mid [\rho_k]_i \to \infty \}, \quad I_a = \{ i \in \{1, \ldots, m\} \mid [\rho_k]_i \text{ is bounded} \},
$$

$$
\rho_k = \min_{i \in I_\infty} \{ [\rho_k]_i \}, \quad \eta_k = \sum_{i \in I_a} |h_i(x_k)|.
$$

The following result corresponds to Lemmas 4.3 and 5.1 of [11], adapted for several penalty parameters.

**Lemma 5.3.** Assume that the sequence $\{x_k\}$ is computed by Algorithm 2. There exists $k_0 \in \mathbb{N}$ and positive constants $b_1, b_2, \bar{m}, \alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5$ such that, for all $k \geq k_0$,

$$
\| \lambda_{k+1} - \lambda_* \|_\infty \leq b_1 \varepsilon_k + b_2 \| x_k - x_* \|_\infty. \tag{46}
$$

If $[\rho_{k_0}]_i \geq \bar{m}$ for all $i \in I_\infty$, then

$$
\| x_k - x_* \|_\infty \leq \alpha_1 \varepsilon_k + \alpha_2 \eta_k + \alpha_3 \sum_{i \in I_\infty} \frac{|[\lambda_k]_i - [\lambda_*]_i|}{[\rho_k]_i} \tag{47}
$$

and

$$
\| \lambda_{k+1} - \lambda_* \|_\infty \leq \alpha_4 \varepsilon_k + \alpha_5 \| h(x_k) \|_\infty. \tag{48}
$$

**Proof.** The proof of (46) is identical to the one of (39).

Using the definition of $G_2(x_k, \bar{x}_k, \rho_k)$, defining $I_F$ as in the formula (5.6) of [11] and taking $\Delta x_k = \| (x_k - x_*)_{|I_F} \|_2$, we obtain the following version of the inequality (5.27) of Lemma 5.1 of [11]:

$$
\left\| \left( \begin{array}{c} (x_k - x_*)_{|I_F} \\ \lambda_{k+1} - \lambda_* \end{array} \right) \right\|_2 \leq M (b_{14} \varepsilon_k + \| h(x_k) \|_2 + b_{11} (\Delta x_k)^2 + b_{12} \Delta x_k \varepsilon_k + b_{13} \varepsilon_k^2) \tag{49}
$$

for all $k \geq k_0$, with $b_{11} = a_7 + a_9 + a_8 b_2, b_{12} = 2(a_7 + a_9) + a_8 (b_{10} + b_2), b_{13} = a_7 + a_9 + a_8 b_{10}, b_{10} = b_1 + b_2$ and for the constants $a_7, a_8$ and $a_9$ considered in the proof of our Lemma 5.1.

By (8) and (46),

$$
|h_i(x_k)| = \frac{|[\lambda_{k+1}]_i - [\bar{\lambda}_k]_i|}{[\rho_k]_i} \leq \frac{|[\lambda_{k+1}]_i - [\lambda_*]_i| + |[\bar{\lambda}_k]_i - [\lambda_*]_i|}{[\rho_k]_i}
$$

15
\[
\leq \frac{b_1 \varepsilon_k + b_2 \|x_k - x_*\|_2 + |[\bar{\lambda}_k]_i - [\lambda_*]_i|}{|\rho_k|_i}.
\]

Now,
\[
\|h(x_k)\|_2 = \sum_{i \in I_\infty} |b_i(x_k)|^2 + \sum_{i \in I_a} |h_i(x_k)|^2.
\]

So, using that \(\sum_{i=1}^n a_i^2 \leq (\sum_{i=1}^n a_i)^2\) for \(a_i \geq 0, i = 1, \ldots, n\), and the inequality (50) for all \(i \in I_\infty\), we obtain:
\[
\|h(x_k)\|_2 \leq \eta_k + \sum_{i \in I_\infty} \frac{|[\bar{\lambda}_k]_i - [\lambda_*]_i|}{|\rho_k|_i} + |I_\infty| \left(\frac{b_1 \varepsilon_k + b_2 \|x_k - x_*\|_2}{\rho_k}\right).
\]

Recall that
\[
\|x_k - x_*\|_2 \leq \Delta x_k + \varepsilon_k.
\]

By (52), replacing (51) in (49), we get
\[
\left\| \left( \begin{array}{c} (x_k - x_*)[I_F] \\ \lambda_{k+1} - \lambda_* \end{array} \right) \right\|_2 \leq M(b_1 \varepsilon_k + \eta_k + \sum_{i \in I_\infty} \frac{|[\bar{\lambda}_k]_i - [\lambda_*]_i|}{|\rho_k|_i}) \\
+ \tilde{b}_{10} \frac{\varepsilon_k}{\rho_k} + b_2 |I_\infty| \left( \frac{\Delta x_k}{\rho_k} + b_1 \Delta x_k^2 + b_2 \Delta x \varepsilon_k + b_3 \varepsilon_k^2 \right),
\]

where \(\tilde{b}_{10} = |I_\infty| (b_1 + b_2)\).

Now, if \(k\) is large enough,
\[
\varepsilon_k \leq \min\{1, \frac{1}{4M b_{12}}\} \text{ and } \Delta x_k \leq \frac{1}{4M b_{11}}.
\]

Define \(\bar{\rho} = \max\{1, 4|I_\infty| M b_2\}\). If \(k\) is large enough, \([\rho_k]_i \geq \bar{\rho}\) for all \(i \in I_\infty\). By (53) and (54) we get:
\[
\Delta x_k = \|(x_k - x_*)[I_F]\|_2 \leq 4M ((b_1 + \tilde{b}_{10} + b_{13}) \varepsilon_k + \eta_k + \sum_{i \in I_\infty} \frac{|[\bar{\lambda}_k]_i - [\lambda_*]_i|}{|\rho_k|_i})
\]

So, by (52), using the equivalence of norms in \(\mathbb{R}^n\), we obtain:
\[
\|x_k - x_*\|_\infty \leq \alpha_1 \varepsilon_k + \alpha_2 \eta_k + \alpha_3 \sum_{i \in I_\infty} \frac{|[\bar{\lambda}_k]_i - [\lambda_*]_i|}{|\rho_k|_i}
\]

for suitable constants \(\alpha_1, \alpha_2\) and \(\alpha_3\). This proves (47).

Let us now prove (48). Using (54) in the inequality (49) we obtain:
\[
\Delta x_k = \|(x_k - x_*)[I_F]\|_2 \leq \frac{\Delta x_k}{2} + M(b_{13} \varepsilon_k + \|h(x_k)\|_2),
\]

where \(b_{15} = b_{13} + b_{14}\). Therefore,
\[
\Delta x_k \leq 2M(b_{15} \varepsilon_k + \|h(x_k)\|_2).
\]
By (52), (55) and the equivalence of norms in $\mathbb{R}^n$, we obtain:

$$\|x_k - x_*\|_\infty \leq \alpha_6 \varepsilon_k + \alpha_7 \|h(x_k)\|_\infty$$

(56)

for suitable constants $\alpha_6$ and $\alpha_7$.

Replacing (56) in (46) and using again the equivalence of norms in $\mathbb{R}^n$, we obtain the inequality

$$\|\lambda_{k+1} - \lambda_*\|_\infty \leq \alpha_4 \varepsilon_k + \alpha_5 \|h(x_k)\|_\infty$$

for suitable constants $\alpha_4$ and $\alpha_5$. Then, (48) is proved. \hfill \square

**Lemma 5.4.** Assume that the sequence $\{x_k\}$ is computed by Algorithm 2. Then, there exists $k_0 \in \mathbb{N}$ such that, for all $k \geq k_0$, \n
$$\bar{\lambda}_k = \lambda_k.$$

**Proof.** By (46), the proof is the same of Lemma 5.2. \hfill \square

**Theorem 5.2.** Assume that the sequence $\{x_k\}$ is computed by Algorithm 2 and that $\varepsilon_k$ is such that

$$\varepsilon_k = \min \{\varepsilon_{k-1}, \|h(x_k)\|_\infty, \varepsilon'_k\}$$

(57)

where $\{\varepsilon'_k\}$ is a decreasing sequence that converges to zero. Then the sequence $\{\rho_k\}$ is bounded.

**Proof.** Suppose that $I_\infty \neq \emptyset$. Let $i_0 \in I_\infty$.

For all $i \in I_a$ there exists $k_1(i)$ such that for all $k \geq k_1(i)$, $[\rho_{k+1}]_i = [\rho_k]_i$. If $k$ is large enough we have that, for all $i \in I_a$,

$$|h_i(x_k)| \leq \tau \|h(x_{k-1})\|_\infty.$$

Then,

$$\eta_k = \sum_{i \in I_a} |h_i(x_k)| \leq |I_a| \tau \|h(x_{k-1})\|_\infty. \quad (58)$$

Let $k \geq \tilde{k} = \max_{i \in I_a} \{k_0, k_1(i)\}$, where $k_0$ is obtained as in Lemma 5.4.

By (8),

$$|h_{i_0}(x_k)| = \left\lfloor \frac{[\lambda_{k+1}]_{i_0} - [\lambda_k]_{i_0}}{[\rho_k]_{i_0}} \right\rfloor \leq \frac{[\lambda_{k+1}]_{i_0} - [\lambda_k]_{i_0}}{[\rho_k]_{i_0}} + \frac{[\lambda_k]_{i_0} - [\lambda_*]_{i_0}}{[\rho_k]_{i_0}}.$$

So, by (46),

$$|h_{i_0}(x_k)| \leq \frac{b_1 \varepsilon_k + b_2 \|x_k - x_*\|_\infty + [\lambda_k]_{i_0} - [\lambda_*]_{i_0}}{[\rho_k]_{i_0}}.$$

Thus, by (47),

$$|h_{i_0}(x_k)| \leq \frac{1}{[\rho_k]_{i_0}} \left\lfloor (b_1 + b_2 \alpha_1) \varepsilon_k + b_2 \alpha_2 \eta_k + b_2 \alpha_3 \sum_{i \in I_a} \frac{[\lambda_k]_i - [\lambda_*]_i}{[\rho_k]_i} \right\rfloor + [\lambda_k]_{i_0} - [\lambda_*]_{i_0}.$$

17
Now, by (48) with $\lambda_k$ replacing $\lambda_{k+1}$, (57) implies that
\[
\|\lambda_k\|_\infty - [\lambda_k]_i \leq \|\lambda_k - \lambda_\ast\|_\infty \leq (\alpha_4 + \alpha_5) \|h(x_{k-1})\|_\infty \quad i = 1, \ldots, m. \tag{59}
\]
Since $\varepsilon_k \leq \varepsilon_{k-1} \leq \|h(x_{k-1})\|_\infty$, combining (58)-(59) we obtain:
\[
|h_{k_0}(x_k)| \leq m_k(i_0) \|h(x_{k-1})\|_\infty,
\]
where
\[
m_k(i_0) = \frac{\hat{m}}{|\rho_k|_{i_0}}
\]
and $\hat{m} > 0$.

Since $m_k(i_0) \to 0$, there exists $\tilde{k}(i_0) \geq k$ such that
\[
|h_{k_0}(x_k)| \leq \tau \|h(x_{k-1})\|_\infty
\]
for all $k \geq \tilde{k}(i_0)$. Therefore, $|\rho_{k+1}|_{i_0} = |\rho_k|_{i_0}$. This is a contradiction. \hfill \Box

6 Numerical experiments

Our main objective regarding this set of experiments is to decide between Algorithm 1 and Algorithm 2. From the theoretical point of view, Algorithm 1 has the advantage that the set of possible infeasible limit points seems to be smaller than the set of possible infeasible limit points of Algorithm 2. Thus, in principle, Algorithm 2 might converge to infeasible points more often than Algorithm 1. On the other hand, Algorithm 2 tends to increase the penalty parameters less frequently than Algorithm 1, a fact that has a positive influence on the conditioning of the subproblems.

However, we are also interested in testing several different options for the implementation of the algorithms. Namely: the best values for $\bar{\lambda}_{\text{min}}$ and $\bar{\lambda}_{\text{max}}$ (large or small?), the best value for the tolerance $\tau$ that determines the increase of penalty parameters and the strategy for choosing $\varepsilon_k$.

Summing up, the practical algorithms to be tested are defined by:

1. Strategy for updating penalty parameters
   
   Option ONE: Algorithm 1.
   Option TWO: Algorithm 2.

2. Choice of the safeguarded Lagrange multiplier approximations
   
   Option BIG: $\bar{\lambda}_{\text{max}} = -\bar{\lambda}_{\text{min}} = 10^{20}$.
   Option SMALL: $\bar{\lambda}_{\text{max}} = -\bar{\lambda}_{\text{min}} = 10^{6}$.

3. Tolerance for improvement of feasibility
   
   Option TIGHT: $\tau = 0.1$.
   Option LOOSE: $\tau = 0.5$.  

18
4. **Strategy for convergence criterion of subproblems**

Option FIX: \( \varepsilon_k = \varepsilon_{\text{min}} \geq 0 \) for all \( k \).

Option INEX: \( \varepsilon_k = \max\{0.1^k, \varepsilon_{\text{min}}\} \) for all \( k \).

Option ADPT: \( \varepsilon'_k = \max\{0.1^k, \varepsilon_{\text{min}}\} \) for all \( k \),

\[
\varepsilon_k = \max\{\varepsilon_{\text{min}}, \min\{\varepsilon'_k, \|h(x_k)\|_\infty\}\}
\]

for Algorithm 1 and

\[
\varepsilon_k = \max\{\varepsilon_{\text{min}}, \min\{\varepsilon_{k-1}, \varepsilon'_k, \|h(x_k)\|_\infty\}\}
\]

for Algorithm 2.

Therefore, 24 different methods are defined. Observe that, when \( \varepsilon_{\text{min}} = 0 \), the option ADPT corresponds to the theoretical hypotheses used in Section 4 to prove boundedness of the penalty parameters. Obviously, in practical (floating point) computations we must choose some small \( \varepsilon_{\text{min}} > 0 \).

The implementation decisions that are common to all the options were the following:

1. For solving the box-constrained minimization subproblems (10) and (11) at Step 2 of both algorithms we used GENCAN [4] with its default parameters. The resulting code (Augmented Lagrangian with GENCAN) will be called ALGENCAN.

2. We computed the Lagrange multipliers estimates using (4), (8) and (38).

3. We set \( \rho_1 = 10 \) for Algorithm 1, \( [\rho_1]_i = 10 \) for all \( i \) for Algorithm 2 and \( \gamma = 10 \) for both algorithms.

4. The algorithms were stopped declaring *Convergence* when

\[
\|P_{\Omega}(x_k - F(x_k) - \nabla h(x_k)\lambda_{k+1}) - x_k\|_\infty \leq \varepsilon_{\text{min}}
\]

and

\[
\|h(x_k)\|_\infty \leq \varepsilon_{\text{min}}.
\]

We used \( \varepsilon_{\text{min}} = 10^{-4} \).

5. An execution is stopped declaring *Time exceeded* if the algorithm runs during 10 minutes without achieving *Convergence*. Other stopping criteria were inhibited in order to ensure an homogeneous comparison.

All experiments were done in a Sun Fire 880 with 8 900 Mhz UltraSPARC III Processors, 32 Gb of RAM memory, running SunOS 5.8. The codes were written in FORTRAN 77 and compiled with Forte Developer 7 Fortran 95 7.0 2002/03/09. We used the option -O4 to optimize the code.

We considered all the nonlinear programming problems with equality constraints and bounds of the CUTE collection [8]. As a whole, we tried to solve 128 problems.
Consider a fixed problem and let \( x_{\text{final}}^{(M)}, M = 1, \ldots, 24, \) be the final point of method \( M \) applied to that problem. In this numerical study we say that \( x_{\text{final}}^{(M)} \) is feasible if
\[
\left\| h(x_{\text{final}}^{(M)}) \right\|_\infty \leq \varepsilon_{\text{min}}.
\]
We define
\[
f_{\text{best}} = \min_M \left\{ f(x_{\text{final}}^{(M)}) \mid x_{\text{final}}^{(M)} \text{ is feasible} \right\}.
\]
We say that method \( M \) found a solution of the problem if \( x_{\text{final}}^{(M)} \) is feasible and
\[
f(x_{\text{final}}^{(M)}) \leq f_{\text{best}} + 10^{-3}|f_{\text{best}}| + 10^{-6}.
\]
Let \( t^{(M)}, M = 1, \ldots, 24, \) be the computer CPU time that method \( M \) used to arrive to \( x_{\text{final}}^{(M)} \). We define
\[
t_{\text{best}} = \min_M \{ t^{(M)} \mid \text{method } M \text{ found a solution} \},
\]
and we say that method \( M \) is one of the fastests method for the problem when
\[
t^{(M)} \leq t_{\text{best}} + 0.01 \ t_{\text{best}}.
\]
These definitions are the same used in [3] for comparing different Augmented Lagrangian formulae.

We are interested in comparing the 24 variants of Augmented Lagrangian algorithms with respect to Feasibility, Robustness and Efficiency. We say that a particular algorithm is robust for solving some problem if it finds the solution of the problem according to the criterion defined above. We say that it is feasible if it finds a feasible point and we say that it is efficient if it is one of the fastests method for solving the problem. In Table 1 we report, for each combination of parameters, the number of problems in which the corresponding algorithm was robust, feasible and efficient, respectively. More precisely, the symbol \( p(q) \) under column R indicates that the algorithm found the solution of \( q \) problems, according to the criterion above and that its rank with respect to robustness was \( p \). The symbol \( p(q) \) under column F means that the algorithm found a feasible point in \( q \) cases and ranked \( p \) with respect to feasibility. The same symbol under column E means that the algorithm was one of the fastests in \( q \) cases and ranked \( p \) with respect to this criterion.

Some preliminary conclusions may be drawn by inspection of Table 1.

- One of the methods (Algorithm 2 with \( \tau = 0.5, \lambda_{\text{max}} = 10^{20}, \varepsilon_k \equiv \varepsilon_{\text{min}} \) ) appears to be the best one, considering feasibility, robustness and efficiency.

- Algorithm 2 is better than Algorithm 1. This means that using different penalty parameter and increasing separately each of them is better than increasing “all” the penalty parameters when the improvement of just one constraint is not enough, as Algorithm 1 does.

Table 1: Performance of ALGECAN
- In general, using a fixed small convergence criterion in the subproblems \( \varepsilon_k = \varepsilon_{\text{min}} \) is better than using inexact choices of \( \varepsilon_k \) at least in terms of efficiency. With respect to feasibility and robustness the different choices of \( \varepsilon_k \) are equivalent.

- The option LOOSE for increasing the penalty parameter is slightly better than the option TIGHT. It is not be very relevant the choice of \( \lambda_{\text{max}} \) between \( 10^6 \) and \( 10^{20} \). Preliminary experiments showed that smaller values of \( \lambda_{\text{max}} \) are not convenient.

In order to test the consistency of our algorithms we compared our winner Augmented Lagrangian algorithm with the default version of LANCELOT [11] and with the same version with true Hessians and without preconditioners. The last one is more adequate since the version of GENCAN that we use does not use preconditioners at all. It must be observed that GENCAN does not use true Hessians either. Matrix-vector products involving Hessians are replaced by incremental gradient quotients in GENCAN. ALGENCAN was more efficient and robust than the version of LANCELOT without preconditioners. It was also more efficient than the preconditioned LANCELOT but not as robust as this method. The corresponding performance profile [14] is shown in Figure 1.

7 Conclusions

Augmented Lagrangian methods are useful tools for solving many practical nonconvex minimization problems with equality constraints and bounds. Its extension to KKT systems and, in consequence, to a wide variety of equilibrium problems (see [18, 20, 21, 23, 26, 27, 36]) is straightforward. We presented two Augmented Lagrangian algorithms for this purpose. They differ only in the way in which penalty parameters are updated. There seems to be an important difference between these two algorithms with respect to convergence properties. According to our feasibility results the set of possible infeasible limit points of Algorithm 1 seems to be strictly contained in the set of possible infeasible limit points of Algorithm 2. This could indicate that Algorithm 2 converges to infeasible points more frequently than Algorithm 1. However, this property was not confirmed by numerical experiments, which clearly indicate that Algorithm 2 is better. So, it seems that maintaining moderate values of the penalty parameters is the more important feature for explaining the practical performance. However, it is still an open problem if stronger results than Theorem 3.2 can be obtained for Algorithm 2.

The question about convergence to optimal (KKT) points is also relevant. Up to our knowledge, convergence to KKT points of algorithms of this type had been obtained only using regularity assumptions (linear independence of active constraints). Here we proved that a much better constraint qualification (CPLD) can be used with the same purpose. Again, the problem of finding even weaker constraint qualifications under which convergence to KKT points can be guaranteed remains open.

The superiority of Algorithm 2 over Algorithm 1 in numerical experiments was not a surprise since every optimization practitioner is conscious of the effect of large penalty parameters on the conditioning of the subproblems and, hence, on the overall performance of Augmented Lagrangian and penalty methods. A little bit more surprising was the (slight) superiority of the algorithms based on accurate resolution of the subproblems over the ones based on inexact resolution. Careful inspection of some specific cases lead us to the following explanation for that behavior. On one hand, GENCAN, the algorithm used to solve the subproblems is an inexact-Newton method whose behavior is many times similar to Newton’s method especially when the iterate is close to the solution. This implies that, after satisfying a loose convergence criterion, the amount of effort needed for satisfying a strict convergence criterion is usually small. In these cases it is not worthwhile to interrupt the execution for defining a new subproblem. (One would be “abandoning Newton” precisely in the region where it is more efficient!) On the other hand, the formula used for updating the Lagrange multipliers is a first-order formula motivated by the assumption of exact solution of the subproblems. When the resolution is inexact, other updating formulae ([24], p. 291) might be more efficient (although, of course, more costly).

The conclusion about the relative efficiency of solving accurately or inaccurately the subproblem may change if one uses different box-constrained solvers. The excellent behavior of the spectral gradient method for very large convex constrained minimization [5, 6, 7, 12, 33, 34] is a strong motivation for pursuing the research on inexact stopping criteria for the subproblems, since in this case quadratic or superlinear convergence is not expected.

Valuable research has been done in the last 10 years in Augmented Lagrangian methods for solving quadratic problems originated in mechanical applications [15, 16, 17]. Adaptive criteria that depend on feasibility of the current point (as in the assumptions of our penalty
boundedness theorems) have been successfully used and justified from several different points of view. (Antecedents of these practical strategies can be found in [25].) More recently [15], Dostál showed that, for some convex quadratic programming problems, an updating strategy based on the increase of the Augmented Lagrangian function have interesting theoretical and practical properties. Extension of his philosophy to the general nonquadratic and nonconvex case must be investigated.

The recent development of efficient sequential quadratic programming, interior-point and restoration methods for nonlinear programming motivates a different line of Augmented Lagrangian research. The “easy” set $\Omega$ does not need to be a box and, in fact, it does not need to be “easy” at all if a suitable algorithm for minimizing on it is available. (The case in which $\Omega$ is a general polytope was considered in [10].) However, many times the intersection of $\Omega$ with the general constraints $h(x) = 0$ is very complicate. In these cases, using the Augmented Lagrangian approach to deal with the general constraints and a different nonlinear programming algorithm to deal with the subproblems is attractive. Certainly, this have been done in practical applications for many years. The convergence properties of these combinations using weak constraint qualifications deserve to be studied.

We presented our methods and theory considering KKT systems and not merely minimization problems to stress the applicability of the Augmented Lagrangian strategy to the general KKT case. We performed several experiments for general KKT systems, where the algorithm used for solving the subproblems was the well known PATH solver (see [13]). We compared the resulting algorithm with the PATH method for solving directly the original problem. On one hand, we confirmed the following warning of [22]: “Typically, singularity of the Jacobian does not cause a lot of problems and the algorithm [PATH] can handle the situation appropriately. However, an excessive number of singularities are cause of concern. A further indication of possible singularities at the solution is the lack of quadratic convergence to the solution”. In fact, for some tested problems, the effect of singularity of the Jacobian was more serious in the direct application of PATH to the original problem than in the “Augmented Lagrangian with PATH” algorithm. In many other situations the direct application of PATH to the KKT system was more efficient. Clearly, the Augmented Lagrangian framework intensely exploits the minimization structure of the problem when the source of the KKT system is nonlinear programming and loses this advantage when the KKT system is general. However, much research is necessary in order to evaluate the potentiality of the Augmented Lagrangian for equilibrium problems, variational inequalities and related problems.
