EXTENDED FORMULATIONS FOR CONVEX HULLS OF SOME BILINEAR FUNCTIONS

AKSHAY GUPTA¹, THOMAS KALINOWSKI²,³, FABIAN RIGTERINK³, AND HAMISH WATERER³

Abstract. We consider the problem of characterizing the convex hull of the graph of a bilinear function \( f \) on the \( n \)-dimensional unit cube \([0, 1]^n\). Extended formulations for this convex hull are obtained by taking subsets of the facets of the Boolean Quadric Polytope (BQP). Extending existing results, we propose a systematic study of properties of \( f \) that guarantee that certain classes of BQP facets are sufficient for an extended formulation. We use a modification of Zuckerberg’s geometric method for proving convex hull characterizations [Geometric proofs for convex hull defining formulations, Operations Research Letters 44 (2016), 625–629] to prove some initial results in this direction. In particular, we provide small-sized extended formulations for bilinear functions whose corresponding graph is either a cycle with arbitrary edge weights or a clique or an almost clique with unit edge weights.

1. Introduction

An important technique in global optimization is the construction of convex envelopes for nonconvex functions, and there is a significant amount of literature on characterizing convex hulls of graphs of nonlinear functions, beginning with [Rik97; She97]; see also the book [LS13]. Rikun studies the question when this convex hull is a polyhedron and gives a complete characterization for functions on polyhedral domains. Even if the convex hull is a polyhedron there might be a very large number of facets, and this is reminiscent of a situation which is quite common in combinatorial optimization: for a natural mixed integer programming (MIP) formulation the convex hull of the feasible set can be described explicitly, but it is a polytope whose number of facets is exponential in the instance size. One approach that has been successful in this area is the use of extended formulations [CCZ10]. The basic idea is to introduce more variables in order to reduce the number of constraints. A reformulation of the convex hull with a polynomial number of constraints and polynomially many additional variables is called a compact extended formulation, and this is a key ingredient in so-called lift-and-project methods, and other related MIP formulation techniques [BCC93; SA90]. In this paper, we use a similar technique: instead of describing the convex hull of a graph of a bilinear function in the original variable space, we seek to describe it in a lifted space with as few inequalities as possible.

A bilinear function is a function \( f : [0, 1]^n \to \mathbb{R} \) of the form

\[
 f(x) = \sum_{1 \leq i < j \leq n} a_{ij} x_i x_j
\]

with coefficients \( a_{ij} \in \mathbb{R} \). The convex hull of the graph of \( f \) is the set

\[
 X(f) := \text{conv}\{(x, z) \in [0, 1]^n \times \mathbb{R} : z = f(x)\},
\]

which is a polytope since
\[ X(f) = \text{conv}\{ (x, z) \in [0, 1]^n \times \mathbb{R} : z = f(x) \} \] (1)
which was proved in [Rik97; She97]. These functions arise in many problem areas; see [DG15; Gup+13; Gup+17] and the references therein.

For bilinear functions, a natural setting for an extended formulation is to introduce additional variables \( y_{ij} \) representing the product \( x_i x_j \) of two original variables for \( a_{ij} \neq 0 \). The classical McCormick inequalities [McC76] for relaxing each bilinear term are
\[ y_{ij} \geq 0, \quad y_{ij} \leq x_i, \quad y_{ij} \leq x_j, \quad x_i + x_j - y_{ij} \leq 1, \] (2)
and they are exact at 0–1 points, that is, they imply \( y_{ij} = x_i x_j \) when \( x_i, x_j \in \{0, 1\} \). The McCormick relaxation is the polytope
\[ M := \{(x, y, z) \in [0, 1]^{(n+1)/2} \times \mathbb{R} : z = \sum_{1 \leq i < j \leq n} a_{ij} y_{ij}, \text{ for all } 1 \leq i < j \leq n\}, \]
whose projection is typically a relaxation of \( X(f) \). The cases where the projection of \( M \) is actually equal to \( X(f) \) have been characterized in [MSF15] and independently in [Bol+17], and there are also some results in this regard for multilinear functions [LNL12]. In general, the McCormick relaxation can be quite weak [Bol+17], and the purpose of this paper is to investigate extended formulations for \( X(f) \) obtained as strengthenings of the McCormick relaxation.

As is customary in the literature, let the functions \( \text{vex}[f] : [0, 1]^n \to \mathbb{R} \) and \( \text{cav}[f] : [0, 1]^n \to \mathbb{R} \), denoting the convex and concave envelopes, respectively, of \( f \) over \( [0, 1]^n \), be defined as
\[ \text{vex}[f](x) = \min\{z : (x, z) \in X(f)\}, \quad \text{cav}[f](x) = \max\{z : (x, z) \in X(f)\}, \]
so that \( X(f) = \{(x, z) \in [0, 1]^n \times \mathbb{R} : \text{vex}[f](x) \leq z \leq \text{cav}[f](x)\} \).

Introducing variables \( y_{ij} \) to represent the products \( x_i x_j \), we are interested in describing \( X(f) \) in terms of the \( x \)- and \( y \)-variables. To be more precise, we define a function \( \pi[f] : \mathbb{R}^n \times \mathbb{R}^{n(n-1)/2} \to \mathbb{R}^{n+1} \) by
\[ \pi[f](x, y) = \left( x, \sum_{1 \leq i < j \leq n} a_{ij} y_{ij} \right), \]
and extend it to the power set of \( \mathbb{R}^n \times \mathbb{R}^{n(n-1)/2} \) in the usual way:
\[ \pi[f](P) = \{ \pi[f](x, y) : (x, y) \in P\} \]
for every \( P \subseteq \mathbb{R}^n \times \mathbb{R}^{n(n-1)/2} \). For a polytope \( P \), let the functions \( \text{LB}_P[f] : [0, 1]^n \to \mathbb{R} \) and \( \text{UB}_P[f] : [0, 1]^n \to \mathbb{R} \) be defined as
\[ \text{LB}_P[f](x) = \min \left\{ \sum_{1 \leq i < j \leq n} a_{ij} y_{ij} : (x, y) \in P \right\} = \min\{z : (x, z) \in \pi[f](P)\}, \]
\[ \text{UB}_P[f](x) = \max \left\{ \sum_{1 \leq i < j \leq n} a_{ij} y_{ij} : (x, y) \in P \right\} = \max\{z : (x, z) \in \pi[f](P)\}, \]
respectively, so that
\[ \pi[f](P) = \{(x, z) \in [0, 1]^n \times \mathbb{R} : \text{LB}_P[f](x) \leq z \leq \text{UB}_P[f](x)\}. \] (3)
Our aim is to find a polytope \( P \) such that \( X(f) = \pi[f](P) \), so that this \( P \) is a compact extended formulation. Observe that
\[ X(f) = \pi[f](P) \iff \text{LB}_P[f](x) = \text{vex}[f](x), \quad \text{UB}_P[f](x) = \text{cav}[f](x), \quad \text{for all } x \in [0, 1]^n. \] (4)

There are constructive methods for deriving extended formulations of \( X(f) \) with exponentially many variables and facet-defining inequalities, such as using the extreme point characterization in (1) or the nontrivial approach of using the Sherali-Adams hierarchy [SA90] which can also be applied to more general nonlinear functions [BM14]. We restrict our attention to finding extended formulations in the quadratic space of \((x, y)\) variables.
Padberg [Pad89] introduced the \textit{Boolean Quadric Polytope} (BQP), which is the convex hull of the binary vectors satisfying the McCormick inequalities \((2)\).

\[
QP := \text{conv}\left\{(x, y) \in \{0, 1\}^{n(n+1)/2} : (2) \text{ for all } 1 \leq i < j \leq n\right\}.
\]

Since the McCormick inequalities are exact at 0–1 points, we have

\[
QP = \text{conv}\left\{(x, y) \in \{0, 1\}^{n(n+1)/2} : y_{ij} = x_i x_j \text{ for all } 1 \leq i < j \leq n\right\}.
\]

It follows from \((1)\) that \(QP\) is an extended formulation for \(X(f)\):

\[
X(f) = \pi[f](QP),
\]

so that \((4)\) implies \(\text{vex}[f](x) = \text{LB}_{QP}[f](x)\) and \(\text{cav}[f](x) = \text{UB}_{QP}[f](x)\). In fact, Burer and Letchford [BL09, Proposition 5] showed that

\[
P = \text{conv}\left\{(x, y) \in [0, 1]^{n(n+1)/2} : y_{ij} = x_i x_j \text{ for all } 1 \leq i < j \leq n\right\}.
\]

Padberg [Pad89] also extended the definition of BQP in the following sense:

\[
QP(G) = \text{conv}\{ (x, y) \in \{0, 1\}^{n+m} : (2) \text{ for all } i j \in E \},
\]

where \(G = (V, E)\) is the edge weighted graph associated with the bilinear function \(f\). This graph has the vertex set \(V = [n] = \{1, \ldots, n\}\), the edge set \(E = \{(i, j) : a_{ij} \neq 0\}\), and the edge weights are given by \(a_{ij}\). Note that this construction gives a one-to-one correspondence between bilinear functions and edge weighted graphs (without loops). Also, \(QP = QP(K_n)\) where \(K_n\) is the complete graph, and \(QP(G)\) is the projection of \(QP\) obtained by projecting out \(y_{ij}\)’s corresponding to \(a_{ij} = 0\). Henceforth, we express

\[
f(x) = \sum_{i j \in E} a_{ij} x_i x_j,
\]

where we use \(ij\) instead of \(i, j\) to denote an edge when there is no danger of ambiguity. We call an edge \(ij \in E\) positive if \(a_{ij} > 0\) and negative if \(a_{ij} < 0\). Abusing notation, we sometimes consider \(\pi[f]\) as a function \(\mathbb{R}^{n+m} \rightarrow \mathbb{R}\) where the value of \(m\) is clear from the context (the number of edges in the graph corresponding to the considered function \(f\)). This allows us to write \(X(f) = \pi[f](QP(G))\).

The polytope \(QP\), and in general \(QP(G)\), has an exponential number of facets, not all of which are known and some of the known facets are NP-hard to separate [BM86; DL97; LS14; Pad89]. Furthermore, there are many graphs for which \(QP(G)\) does not have a polynomial-sized extended formulation [AT15]. If we do not assume any structure on \(f\) and allow \(f\) to be arbitrary, then a complete characterization of \(QP(G)\) seems necessary for convexifying \(f\) due to the following observation.

\textbf{Remark 1.} For every facet \(\alpha^T x + \beta^T y \leq \alpha_0\) of \(QP(G)\) there exists a bilinear function \(f\) such that \(\alpha^T x + \beta^T y \leq \alpha_0\) is necessary to describe \(X(f)\) in the sense that \(\pi[f](P) \supseteq X(f)\) for the polytope \(P\) obtained from \(QP\) by omitting \(\alpha^T x + \beta^T y \leq \alpha_0\). To see this, just take \(f(x) = \sum_{i j \in E} \beta_{ij} x_i x_j\). Then \(f(x) \leq \alpha_0 - \alpha^T x\) for every \(x \in [0, 1]^n\), but there exists \((x^*, y^*) \in P\) with \(\alpha^T x^* + \beta^T y^* > \alpha_0\), and therefore \(\pi[f](x^*, y^*) \notin X(f)\).

\textbf{Our approach.} The polytope \(QP(G)\) has a very rich combinatorial structure that is not known explicitly and is even hard to generate algorithmically. Also, since \(QP(G)\) is an extension of \(X(f)\) and two polytopes can project onto the same polytope, it is natural to expect that for certain bilinear functions \(f\), or equivalently weighted graphs \(G\), fully characterizing \(QP(G)\) may be much more than what is actually necessary for convexifying \(f\). These facts motivate us to search for graphs \(G\) for which we can identify polynomial-sized polytopes \(P \supseteq QP(G)\) such that \(\pi[f](P) = X(f)\). We would also like such a \(P\) to be minimal in the following sense. An extended formulation \(P \supseteq QP(G)\) of \(X(f)\) is said to be \textit{minimal} if omitting any facet-defining inequality of \(P\) leads to a polytope \(P' \supseteq P\) with \(\pi[f](P') \supseteq X(f)\). In other words, we want to identify minimal classes of valid inequalities for \(QP\) which still ensure that the polytope defined by these inequalities satisfies \(\pi[f](P) = X(f)\), the motivation being that \(P \subseteq \mathbb{R}^{n(n+1)/2}\) might have significantly fewer facets than \(X(f) \subseteq \mathbb{R}^{n+1}\).
Contributions and Outline. We identify two graph families for which a polynomial number of commonly known valid inequalities for $QP(G)$ are sufficient to convexify the corresponding $f$. These main results are stated in §2.2, following a short description of the valid inequalities considered by us. Another main contribution of this paper is to use a new technique for proving the tightness of our extended formulations. This technique is inspired by a recent work in the literature on geometric characterization of 0–1 polytopes, and is described in §3. We remove some of the technicalities of a result from the literature and apply our simplified result to state a description of the convex hulls of graphs of arbitrary nonlinear, and bilinear, functions over $\{0, 1\}^n$. This is then used to prove our main results in §4. We hope that our successful use of this technique will inspire others to use it to prove more results on extended formulations for $X(f)$ or other combinatorial polytopes.

2. Background and Our Results

To state our main results, we first need to describe the families of valid inequalities and facets of BQP that we are interested in. Other classes of valid inequalities are also available in the literature, many of which are obtained by exploiting the linear bijection between BQP and the cut polytope [BM86; DL97; Sim90]. Separation questions related to some of these inequalities have also been addressed in [LS14].

2.1. Padberg’s inequalities for BQP. The inequalities derived by Padberg [Pad89] can be written down conveniently using the following notation, for $S \subseteq V$, $\hat{E} \subseteq E$:

$$E(S) = \{ij \in E : i, j \in S\}, \quad x(S) = \sum_{i \in S} x_i, \quad y(\hat{E}) = \sum_{ij \in \hat{E}} y_{ij}.$$

The inequalities that are relevant for our results are the following.

Triangle inequalities: for any $i, j, k \in V$,

$$x_i + x_j + x_k - y_{ij} - y_{ik} - y_{jk} \leq 1, \quad (6a)$$
$$-x_i + y_{ij} + y_{ik} - y_{jk} \leq 0, \quad (6b)$$
$$-x_j + y_{ij} - y_{ik} + y_{jk} \leq 0, \quad (6c)$$
$$-x_k - y_{ij} + y_{ik} + y_{jk} \leq 0, \quad (6d)$$

Clique inequalities: for any $S \subseteq V$ with $|S| \geq 3$ and integer $\alpha$, $1 \leq \alpha \leq |S| - 2$,

$$\alpha x(S) - y(E(S)) \leq \frac{\alpha(\alpha + 1)}{2} \quad (7)$$

Cycle inequalities: for every cycle $C \subseteq E$ and every subset $D \subseteq C$ with odd cardinality,

$$x(V_0) - x(V_1) + y(C \setminus D) - y(D) \leq (|D| - 1)/2, \quad (8)$$

where

$$V_0 = \{u \in V : e \cap \hat{e} = \{u\} \text{ for some } e, \hat{e} \in D\},$$
$$V_1 = \{u \in V : e \cap \hat{e} = \{u\} \text{ for some } e, \hat{e} \in C \setminus D\}.$$

Using only subsets of the known facets of $QP$, one can define different relaxations, and there exist a number of results on conditions on $G$ which guarantee that $QP(G)$ is equal to certain relaxations. The LP relaxation of $QP(G)$ is the polytope in $[0, 1]^{n+|E|}$ defined by the McCormick inequalities (2). Padberg showed this is equal to $QP(G)$ if and only if $G$ is acyclic. The cycle relaxation of $QP(G)$, which is a strengthening of the McCormick relaxation by adding cycle inequalities (8) for each chordless cycle $C \subseteq E$ and each subset $D \subseteq C$ with $|D|$ odd, is equal to $QP(G)$ if and only if $G$ is $K_4$-minor-free (series-parallel graphs) [Pad89; Sim90].

More characterizations for the cycle relaxation were obtained recently by [Mic18]. Another set of known results about Padberg’s inequalities is that the triangle inequalities give the Chvátal-Gomory closure of the LP relaxation of $QP(K_n)$ [BCH92], and this was recently generalized to the odd cycle inequalities giving the Chvátal-Gomory closure of the LP relaxation of $QP(G)$ for arbitrary $G$ [BGL18].
All of these literature results are about characterizing $QP(G)$, which, as we have explained in the introduction, might sometimes be more than what is required for convexifying $f$. One of our main results is that if $G$ is a chordless cycle of length $n$, which is $K_n$-minor-free and so the corresponding $f$ is convexified by all the $2^{n-1}$-cycle inequalities (8), then only two cycle inequalities are needed to get a polytope $P$ with $\pi[f](P) = X(f)$. This extends to cactus graphs, that is, graphs in which every edge is contained in at most one cycle. The next section presents precise statements of our results. We clarify that none of these results implies anything about the description of $QP(G)$.

2.2. Main results. When $f(x) = \sum_{1 \leq i < j \leq n} x_i x_j$, so that the corresponding graph is the complete graph $K_n$ with all edge weights equal to 1, then it is known that the McCormick inequalities $y_{ij} \leq \min \{x_i, x_j\}$ together with the clique inequalities (7) with $S = V$ suffice to describe the convex hull of the graph of $f$. In fact, this implies that the only lower bounds on the $y$-variables come from inequalities which can be written in the form $y(E) \geq \ldots s x(V) - (\frac{s+1}{2})$, so the convex envelope $\text{vex}[f]$ can be written in terms of the original variables $x_1, \ldots, x_n$ and $z = y(E)$, and this is precisely the convex envelope characterization proved in [Rik97; She97]. We provide an alternative proof of this result in §3.2. As an extension, our first main result addresses the case of $K_n^-$, which is the graph obtained from $K_n$ by deleting the edge between $n - 1$ and $n$, with unit weights, for which the bilinear function is $f(x) = \sum_{1 \leq i < j \leq n-1} x_i x_j + \sum_{i=1}^{n-2} x_i x_n$.

**Theorem 1** (Almost complete). If $G = K_n^-$ and all edge weights are equal to 1, then $X(f) = \pi[f](P)$ where $P \subseteq [0,1]^{(n+1)/2}$ is described by $y(E) \geq 0$, the McCormick inequalities $y_{ij} \leq x_i$ and $y_{ij} \leq x_j$ for $1 \leq i < j \leq n$, together with the $3(n - 2)$ inequalities

\[
s x \left( V \setminus \{n-1,n\} \right) + \frac{x_{n-1} + x_n}{2} \leq 2, \quad i = 1, \ldots, n - 2 \tag{9}
\]

\[
- y \left( E \left( V \setminus \{n-1,n\} \right) \right) - \frac{1}{2} \sum_{i=1}^{n-2} (y_{i,n-1} + y_{in}) \leq \left( \frac{s+1}{2} \right), \quad s = 1, \ldots, n - 2, \tag{10}
\]

\[
s x(V) - y(E) - y_{n-1,n} \leq \left( \frac{s+1}{2} \right), \quad s = 1, \ldots, n - 2. \tag{11}
\]

Moreover, this polytope $P$ is a minimal extension of $X(f)$.

Constraints (9) are sums of McCormick inequalities $x_i + x_{n-1} - y_{i,n-1} \leq 1$ and $x_i + x_n - y_{in} \leq 1$. The other inequalities in the above theorem come from Padberg’s clique inequalities: (10) are the averages of the clique inequalities for the two maximal cliques in $G$ and (11) are the clique inequalities for $K_n$. It should be of no surprise that the non-McCormick inequalities required to describe $X(f)$ all have negative coefficients on the $y$ variables, because only $\text{vex}[f](x)$ is unknown since two of the McCormick inequalities for every $y_{ij}$ are known to describe $\text{cav}[f](x)$ when edge weights are non-negative ([LAN12; TRX12], see also Corollary 2 below). An interesting feature of this theorem is that the variable $y_{n-1,n}$ is used although it does not correspond to an edge in $G$. The point in Figure 1 illustrates that the clique inequalities for the cliques in the given graph are not sufficient in general. The point satisfies the clique inequalities for the seven 3-cliques, and for the two 4-cliques, as well as the cycle inequalities for all cycles in $K_5^-$, but $\pi[f](x, y) = (1/2, 1/2, 1/2, 3/4, 1/4, 3/2) \notin X(f)$, because it violates the inequality

\[
2(x_1 + x_2 + x_3 + x_4) + x_5 - z \leq 3
\]

which can be obtained by using $y_{45} \leq x_5$ to eliminate $y_{45}$ from a clique inequality for the $K_5$. 
From Theorem 1, we can also read off a description of $\text{vex}[f](x)$ in terms of the original variables: $\text{vex}[f](x) = \max\{0, z_1, z_2\}$, where

$$z_1 = \max \left\{sx(V) - \min\{x_{n-1}, x_n\} - \frac{(s+1)}{2} : 1 \leq s \leq n-2 \right\},$$

$$z_2 = \max \left\{s \left[x(V \setminus \{n-1, n\}) + \frac{x_{n-1} + x_n}{2} - \frac{(s+1)}{2}\right] + \frac{1}{2} \sum_{i=1}^{n-2} \max\{0, 2x_i + x_{n-1} + x_n - 2\} : 1 \leq s \leq n-2 \right\}.$$

The second main result is about chordless cycles. Let $C_n$ denote an $n$-cycle with edges $\{i, i+1\}$ for $i \in [n-1]$, and the edge $\{1, n\}$. The vertex set and edge set are each in bijection with $[n]$ and hence indexed by $[n]$. For ease of notation, all indices have to be read modulo $n$ in the obvious way. In particular, $n \equiv 0$ and $n + 1 \equiv 1$. For $i = 1, \ldots, n$, edge $\{i, i+1\}$ is referred to as edge $i$ and $a_{i,i+1}$ is written as $a_i$. The index set $[n]$ can be partitioned as $[n] = E^- \cup E^+$ based on the signs of the coefficients:

$$E^- = \{i : a_i < 0\}, \quad E^+ = \{i : a_i > 0\}.$$  

We define $V^-$ (resp. $V^+$) to be the set of vertices $i \in [n]$ such that both of the edges incident with $i$ correspond to negative (resp. positive) terms in $f(x)$. More formally,

$$V^- = \{i \in [n] : (i-1, i) \subseteq E^\prime\}, \quad V^+ = \{i \in [n] : (i-1, i) \subseteq E^\prime\},$$

which, in general, may not partition $[n]$.

**Theorem 2** (Cycles). For $G = C_n$, we have $\pi[f](P) = X(f)$ where $P \subseteq [0, 1]^{2n}$ is the polytope described by the McCormick inequalities (2) and

$$x(V^-) - x(V^+) + y(E^+) - y(E^-) \leq \left\lfloor \frac{|E^-|}{2} \right\rfloor,$$  

and

$$x(V^+) - x(V^-) + y(E^-) - y(E^+) \leq \left\lfloor \frac{|E^+|}{2} \right\rfloor.$$  

Moreover, inequality (12) (resp. (13)) can be omitted if and only if $|E^-|$ (resp. $|E^+|$) is even, and then $P$ is a minimal extension of $X(f)$.

The polytope $P$ in Theorem 2 is parametrized by edge weights $a$ and should be read as $P_a$, since (12) and (13) are constructed using the sign pattern on the edge weights. Obviously, since $P$ has only two cycle inequalities, it is a weak relaxation of $QP(C_n)$, which we know is
given by all the $2^{n-1}$ odd-cycle inequalities due to $C_n$ being $K_n$-minor-free. When $|E^-|$ is odd, 
inequality (12) is Padberg’s cycle inequality (8) corresponding to the odd subset $D = E^- \subseteq G$ in the graph $C_n$. This is because $D = E^- = E(C_n) \setminus E^+$ and every vertex in $C_n$ having exactly two edges incident on it implies that $V_0 = V^-$ and $V_1 = V^+$. If $|E^-|$ is even, we will show in the proof of Theorem 2 that inequality (12) is a linear combination of McCormick inequalities. Analogous arguments hold for $E^+$ and (13). Note that inequalities (12) and (13) do not use any non-edge variables $y_{ij}$; in contrast, Theorem 1 presents a minimal extension for the chordal graph $K_n$ using a non-edge variable $y_{n-1,0}$.

Theorem 2 implies that if the bilinear function corresponds to an even cycle $C_n$ having both $|E^+|$ and $|E^-|$ even, then the McCormick inequalities are sufficient to convexify the function. This implication is a special case of the following characterization by Boland et al. [Bol+17, Theorem 4]: for any bilinear function $f$, the McCormick relaxation projects onto $X(f)$ if and only if every cycle in the graph $G$ of $f$ has both $|E^+|$ and $|E^-|$ even. This naturally raises the question of what can be said about bilinear functions with odd cycles. In general, we should not expect to convexify a bilinear function using extended formulation for each cycle in the function, since the function may have large extension complexity, whereas any cycle has a small extended formulation given in Theorem 2. However, we show that for cactus graphs, which are graphs whose cycles are edge-disjoint, or equivalently, any two cycles have at most one common vertex, the bilinear function is convexified by considering each cycle individually.

**Theorem 3.** If $G$ is a cactus with $k$ cycles, then for any edge weight vector $a$, $X(f)$ is described by the McCormick inequalities and at most $2k$ cycle inequalities.

This result is argued using the following consequence of the method described in Section 3: if $f$ and $g$ are two bilinear functions which share at most one variable, then $X(f + g)$ can be easily described in terms of $X(f)$ and $X(g)$ (see Corollary 3 for a precise statement).

We conclude this section by illustrating the reduction in the number of required inequalities for small examples. In Table 1 we compare the numbers of facets of $X(f) \subseteq \mathbb{R}_n$ to the numbers of inequalities describing a polytope $P \subseteq \mathbb{R}_n$ with $\pi[f](P) = X(f)$. The facet numbers for $X(f)$ are determined using polymake [Ass+17], while the numbers in the columns for the polytopes $P$ are determined as follows. For $G = K_n$ with unit coefficients, we can choose $P \subseteq \mathbb{R}_n$ described by the following $n(n + 2)$ inequalities:

- $2n$ variable bounds $0 \leq x_i \leq 1$ for $i \in [n]$,
- $n(n - 1)$ McCormick upper bounds $y_{ij} \leq x_i$ and $y_{ij} \leq x_j$ for $ij \in E$,
- $n - 1$ inequalities $y(E) \geq s x(V) - s(s + 1)/2$ for $s \in [n - 1]$, and
- one inequality $y(\emptyset) \geq 0$.

For $G = K_n$ with unit coefficients, the following $n^2 + 4n - 4$ inequalities are sufficient:

- $2n$ variable bounds $0 \leq x_i \leq 1$ for $i \in [n]$,
- $n(n - 1)$ McCormick inequalities $y_{ij} \leq x_i$ and $y_{ij} \leq x_j$,
- $3n - 6$ inequalities (9), (10), (11),

Table 1. Numbers of facets for $X(f)$ and for our extended formulations.
• one inequality $y(E) \geq 0$.

For $G = C_n$, with arbitrary coefficients, the following $6n + 2$ inequalities are sufficient:

• 2n variable bounds $0 \leq x_i \leq 1$ for $i \in [n]$,  

• 4n McCormick inequalities (2), and

• two inequalities (12) and (13).

3. A Geometric Characterization of Combinatorial Polytopes

3.1. Zuckerberg’s method. Zuckerberg [Zuc04; Zuc16] developed a technique to prove convex hull characterizations for subsets of $\{0, 1\}^n$. In this section, we simplify one of the technical results from this work and extend it to the convex hulls of graphs of arbitrary functions $\psi : \{0, 1\}^n \to \mathbb{R}$.

We are interested in the convex hull of a set $\mathcal{F} \subseteq \{0, 1\}^n$. Any such $\mathcal{F}$ can be represented as a finite combination of unions, intersections and complementations of the sets

$$A_i = \{ \xi \in \{0, 1\}^n : \xi_i = 1 \}, \quad i = 1, \ldots, n,$$

and we fix such a representation $F(A_1, \ldots, A_n)$. For instance, the set $X(f)$ for the function $f : [0, 1]^2 \to [0, 1]$ given by $f(x_1, x_2) = x_1 x_2$ is the convex hull of the set

$$\mathcal{F} = \{ (0, 0, 0), (0, 1, 0), (1, 0, 0), (1, 1, 1) \},$$

which is given by the variable bounds $0 \leq x_1, x_2, x_3 \leq 1$ and the McCormick inequalities

$$x_3 \leq x_1, \quad x_3 \leq x_2, \quad x_3 \geq x_1 + x_2 - 1.$$  

In this case $\mathcal{F}$ can be represented as

$$\mathcal{F} = F(A_1, A_2, A_3) = (A_1 \cap A_2 \cap A_3) \cup (A_1 \cup A_2 \cup A_3) \cup (A_1 \cap A_2 \cup A_3) \cup (A_2 \cap A_1 \cup A_3),$$

where $\overline{\cdot}$ indicates the complement in $\{0, 1\}^3$.

The main result in [Zuc16, Theorem 7] can be stated as follows. For every $x \in [0, 1]^n$, we have $x \in \text{conv}($\mathcal{F}$)$ if and only if there exist

• a set $U$ with a collection $\mathcal{L}$ of subsets which contains the empty set and is closed under taking complements and finite unions, and

• a function $\mu : \mathcal{L} \to \mathbb{R}$ with $\mu(U) = 1$ and $\mu(L_1 \cup \cdots \cup L_k) = \mu(L_1) + \cdots + \mu(L_k)$ for any finite collection of pairwise disjoint elements $L_1, \ldots, L_k \in \mathcal{L}$, and

• sets $X_1, \ldots, X_n \in \mathcal{L}$ with $\mu(X_i) = x_i$ for all $i \in [n]$ and $\mu(F(X_1, \ldots, X_n)) = 1$ (where the complement has to be taken in $U$ instead of $\{0, 1\}^n$).

To be precise, Zuckerberg states only one direction of this equivalence, but the other one is easy (see the proof of Theorem 4 below).

Example 1. For $\mathcal{F} = \{ (0, 0, 0), (0, 1, 0), (1, 0, 0), (1, 1, 1) \}$ we take $U$ to be the half-open interval $[0, 1)$ with $\mathcal{L}$ being the collection of unions of finitely many half-open intervals and $\mu$ the Lebesgue measure (restricted to $\mathcal{L}$), that is,

$$\mathcal{L} = \{ [a_i, b_i) \cup \cdots \cup [a_k, b_k) : 0 \leq a_1 < b_1 < a_2 < b_2 < \cdots < a_k < b_k \leq 1, \ k \in \mathbb{N} \},$$

$$\mu(X) = (b_i - a_i) + \cdots + (b_k - a_k) \quad \text{for} \ X = [a_1, b_1) \cup \cdots \cup [a_k, b_k) \in \mathcal{L}. $$

For $(x_1, x_2, x_3) \in \text{conv}(\mathcal{F})$ we set

$$X_1 = [0, x_1), \quad X_2 = [x_1 - x_3, x_1 + x_2 - x_3), \quad X_3 = [x_1 - x_3, x_1).$$

Then $\mu(X_i) = x_i$ for all $i \in \{1, 2, 3\}$, and from

$$F(X_1, X_2, X_3) = (X_1 \cap X_2 \cap X_3) \cup (X_1 \cup X_2 \cup X_3) \cup (X_1 \cap X_2 \cup X_3) \cup (X_2 \cap X_1 \cup X_3) \cup (X_1 - x_3, x_1) \cup [x_1 + x_2 - x_3, 1) \cup [0, x_1 - x_3) \cup [x_1, x_1 + x_2 - x_3) = [0, 1)$$

we get $\mu(F(X_1, X_2, X_3)) = 1$, as required. This provides a proof that the McCormick inequalities indeed characterize the convex hull of the set $\{(x_1, x_2) : x_1, x_2 \in [0, 1]\}$. The construction is illustrated in Figure 2 for $x = (0.5, 0.4, 0.1)$. The sets $X_1$, $X_2$ and $X_3$ do not
only provide a certificate that \( x \in \text{conv} F \), but they also encode a representation of \( x \) as a convex combination of the elements of \( F \). To see this we associate with each \( t \in [0,1) \) the vector \( x(t) = (x_1(t), x_2(t), x_3(t)) \) with \( x_i(t) = 1 \) if \( t \in X_i \) and \( x_i(t) = 0 \) if \( t \notin X_i \). In our example

\[
x(t) = \begin{cases} 
(1, 0, 0) & \text{for } t \in X_1 \cap X_2 \cup X_3 = [0, 0.4), \\
(1, 1, 1) & \text{for } t \in X_1 \cap X_2 \cap X_3 = [0.4, 0.5), \\
(0, 1, 0) & \text{for } t \in X_2 \cap X_1 \cup X_3 = [0.5, 0.8), \\
(0, 0, 0) & \text{for } t \in X_1 \cup X_2 \cup X_3 = [0.8, 1),
\end{cases}
\]

which corresponds to the convex representation

\[
\begin{pmatrix} 0.5 \\ 0.4 \\ 0.1 \end{pmatrix} = 0.4 \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} + 0.1 \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} + 0.3 \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} + 0.2 \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}.
\]

(17)

Our main simplification of Zuckerberg’s result is that the statement remains true if \( U \) and \( L \) are fixed as in Example 1. As a consequence, the condition \( \mu(F(X_1, \ldots, X_n)) = 1 \) can be replaced by \( F(X_1, \ldots, X_n) = U \), and in fact, the set theoretic representation of \( F \) can be avoided completely using the standard identification of the elements of \( \{0,1\}^n \) with subsets of \( [n] \). More precisely, a vector \( \xi \in \{0,1\}^n \) is identified with the set \( \{i \in [n] : \xi_i = 1\} \), so that in particular the elements of \( F \) are identified with subsets of \( [n] \). The following theorem is a reformulation of [Zuc16, Theorem 7] which is more convenient for our purpose. We provide a complete proof in our setting because the proof is short and it would be a bit cumbersome to explain in detail how our variant can be obtained from the arguments in [Zuc16]. Following the proof of the theorem we explain in detail how Zuckerberg’s original statement can be obtained as a consequence of our theorem (see Remark 2).

**Theorem 4.** Let \( F \subseteq \{0,1\}^n \), \( x \in \{0,1\}^n \), and let \( L \) and \( \mu \) be defined by (15) and (16). Then \( x \in \text{conv}(F) \) if and only if there are sets \( X_1, \ldots, X_n \in L \) such that \( \mu(X_i) = x_i \) for all \( i \in [n] \), and \( \{i \in [n] : t \in X_i\} \in F \) for every \( t \in [0,1) \).

**Proof.** Let us fix an ordering \( \xi_1, \ldots, \xi_{|F|} \) of \( F \) (in Example 1, the ordering would be the one in which the elements of \( F \) appear in the convex combination (17)), and suppose \( x \in \text{conv}(F) \), say \( x = \lambda_1 \xi_1 + \cdots + \lambda_{|F|} \xi_{|F|} \) with \( \lambda_1 + \cdots + \lambda_{|F|} = 1 \) and \( \lambda_k \geq 0 \) for all \( k \in [|F|] \). We define a partition \( U = I_1 \cup \cdots \cup I_{|F|} \) by setting \( I_1 = [0, \lambda_1) \) and \( I_k = [\lambda_1 + \cdots + \lambda_{k-1}, \lambda_1 + \cdots + \lambda_k) \) for \( k \in \{2, \ldots, |F|\} \). For

\[
X_i = \bigcup_{k : \xi_i^k = 1} I_k,
\]

we have, for every \( i \in [n] \),

\[
\mu(X_i) = \sum_{k : \xi_i^k = 1} \mu(I_k) = \sum_{k : \xi_i^k = 1} \lambda_k = \sum_{k = 1}^{|F|} \lambda_k \xi_i^k = x_i,
\]

and, for every \( t \in [0,1) \), there is a unique index \( k \) with \( t \in I_k \), and then

\[
\{i \in [n] : t \in X_i\} = \{i \in [n] : \xi_i^k = 1\} = \xi_i^k \in F,
\]
as required. Conversely, if \( X_i \) are sets with the described properties, we can set
\[
\lambda_k = \mu \left( \left\{ t : \{ i \in [n] : t \in X_i \} = \xi^k \right\} \right)
\]
for \( k = 1, \ldots, |\mathcal{F}| \) to obtain the required convex representation \( x = \lambda_1 \xi^1 + \cdots + \lambda_{|\mathcal{F}|} \xi^{|\mathcal{F}|} \).
To see this note that by assumption, for every \( t \in [0,1) \), there is a unique \( k \in [|\mathcal{F}|] \) with \( \xi^k = \{ i \in [n] : \xi_i^k = 1 \} \), and then for every \( j \in [n] \), \( t \in X_j \) if and only if \( \xi_j^k = 1 \). In other words,
\[
X_j = \bigcup_{k : \xi_j^k = 1} \left\{ t : \{ i \in [n] : t \in X_i \} = \xi^k \right\},
\]
and using this we can verify that \( \lambda_1 \xi^1 + \cdots + \lambda_{|\mathcal{F}|} \xi^{|\mathcal{F}|} = x \): for every \( j \in [n] \),
\[
\sum_{k=1}^{n} \lambda_k \xi^k = \sum_{k=1}^{n} \mu \left( \left\{ t : \{ i \in [n] : t \in X_i \} = \xi^k \right\} \right) \xi_j^k
\]
\[
= \sum_{k : \xi_j^k = 1} \mu \left( \left\{ t : \{ i \in [n] : t \in X_i \} = \xi^k \right\} \right) = \mu \left( \bigcup_{k : \xi_j^k = 1} \left\{ t : \{ i \in [n] : t \in X_i \} = \xi^k \right\} \right)
\]
\[
= \mu(X_j) = x_j. \quad \square
\]

**Remark 2.** Theorem 4 implies Zuckerberg’s criterion since for any subsets \( X_1, \ldots, X_n \subseteq [0,1) \),
\[
F(X_1, \ldots, X_n) = \{ t \in [0,1) : \{ i \in [n] : t \in X_i \} \in \mathcal{F} \}.
\]
This can be seen by induction on the structure of the formula \( F \). The base case is \( \mathcal{F} = A_j \) for some \( j \in [n] \). Then
\[
F(X_1, \ldots, X_n) = X_j = \{ t \in [0,1) : j \in \{ i \in [n] : t \in X_i \} \}
\]
\[
= \{ t \in [0,1) : \{ i \in [n] : t \in X_i \} \in A_j \},
\]
as required. For the induction step we have either

1. \( \mathcal{F} = F(A_1, \ldots, A_n) = \overline{F}_1(A_1, \ldots, A_n) \), or
2. \( \mathcal{F} = F(A_1, \ldots, A_n) = F_1(A_1, \ldots, A_n) \cup F_2(A_1, \ldots, A_n) \), or
3. \( \mathcal{F} = F(A_1, \ldots, A_n) = F_1(A_1, \ldots, A_n) \cap F_2(A_1, \ldots, A_n) \),

and in each case we can verify the statement.

**Case 1:** \( \mathcal{F} = F_1(A_1, \ldots, A_n) \). By induction,
\[
F_1(X_1, \ldots, X_n) = \{ t \in [0,1) : \{ i \in [n] : t \in X_i \} \in F_1(A_1, \ldots, A_n) \},
\]
and then
\[
t \in F(X_1, \ldots, X_n) \iff t \notin F_1(X_1, \ldots, X_n) \iff \{ i \in [n] : t \in X_i \} \notin F_1(A_1, \ldots, A_n)
\]
\[
\iff \{ i \in [n] : t \in X_i \} \in \overline{F}_1(A_1, \ldots, A_n) = \mathcal{F}.
\]

**Case 2:** \( \mathcal{F} = F_1(A_1, \ldots, A_n) \cup F_2(A_1, \ldots, A_n) \). By induction,
\[
F_k(X_1, \ldots, X_n) = \{ t \in [0,1) : \{ i \in [n] : t \in X_i \} \in F_k(A_1, \ldots, A_n) \},
\]
for \( k \in \{1,2\} \), and then
\[
t \in F(X_1, \ldots, X_n) \iff t \in F_1(X_1, \ldots, X_n) \cup F_2(X_1, \ldots, X_n)
\]
\[
\iff \{ i \in [n] : t \in X_i \} \in F_1(A_1, \ldots, A_n) \cup F_2(A_1, \ldots, A_n) = \mathcal{F}.
\]

**Case 3:** \( \mathcal{F} = F_1(A_1, \ldots, A_n) \cap F_2(A_1, \ldots, A_n) \). By induction,
\[
F_k(X_1, \ldots, X_n) = \{ t \in [0,1) : \{ i \in [n] : t \in X_i \} \in F_k(A_1, \ldots, A_n) \},
\]
for \( k \in \{1,2\} \), and then
\[
t \in F(X_1, \ldots, X_n) \iff t \in F_1(X_1, \ldots, X_n) \cap F_2(X_1, \ldots, X_n)
\]
\[
\iff \{ i \in [n] : t \in X_i \} \in F_1(A_1, \ldots, A_n) \cap F_2(A_1, \ldots, A_n) = \mathcal{F}.
\]
Let us define two functions \( \psi : [0, 1]^n \to \mathbb{R} \). For every function \( \psi \) it follows that 

\[
\xi = \min \left\{ \sum_{k \in \{0, 1\}^n} \mu(k \cdot \psi(X_1, \ldots, X_n)) : \mu(X_i) = x_i \text{ for all } i \in [n] \right\},
\]

\[
\xi = \max \left\{ \sum_{k \in \{0, 1\}^n} \mu(k \cdot \psi(X_1, \ldots, X_n)) : \mu(X_i) = x_i \text{ for all } i \in [n] \right\}.
\]

**Theorem 5.** For every function \( \psi : [0, 1]^n \to \mathbb{R} \),

\[
X(\psi) = \left\{ (x, z) \in [0, 1]^n \times \mathbb{R} : \psi_-(x) \leq z \leq \psi_+(x) \right\}.
\]

**Proof.** First suppose \((x, z) \in X(\psi)\), say

\[
(x, z) = \sum_{k=1}^{2^n} \lambda_k \left( \xi^k, \psi \left( \xi^k \right) \right),
\]

where \(\xi^1, \ldots, \xi^{2^n}\) is a fixed ordering of \([0, 1]^n\). The sets \(X_i \in \mathcal{L}\) with \(\mu(X_i) = x_i\) are defined exactly as in the proof of Theorem 4: For the partition \(U = I_1 \cup \cdots \cup I_{2^n}\) with \(I_1 = [0, \lambda_1]\) and 

\[
I_k = [\lambda_1 + \cdots + \lambda_{k-1}, \lambda_1 + \cdots + \lambda_k)
\]

for \(k \in \{2, \ldots, 2^n\}\), we set

\[
X_i = \bigcup_{k : \xi^k_i = 1} I_k.
\]

For every \(k \in \{2^n\}, R_{\psi^k}(X_1, \ldots, X_n) = I_k\), hence \(\mu(R_{\psi^k}(X_1, \ldots, X_n)) = \lambda_k\). With

\[
z = \sum_{k=1}^{2^n} \lambda_k \psi \left( \xi^k \right) = \sum_{k=1}^{2^n} \mu \left( R_{\psi^k}(X_1, \ldots, X_n) \right) \psi \left( \xi^k \right)
\]

it follows that \(\psi_-(x) \leq z \leq \psi_+(x)\).

For the converse, suppose \(\psi_-(x) \leq z \leq \psi_+(x)\), and let \((X_1, \ldots, X_n)\) and \((X'_1, \ldots, X'_n)\) be optimizers for the problems defining \(\psi_-(x)\) and \(\psi_+(x)\), respectively. We write \(z = t \psi_-(x) + (1-t) \psi_+(x)\) for some \(t \in [0, 1]\), and set

\[
\lambda(\xi) = t \mu(R_{\psi}(X_1, \ldots, X_n)) + (1-t) \mu(R_{\psi}(X'_1, \ldots, X'_n))
\]

for all \(\xi \in \{0, 1\}^n\). This gives the required convex representation

\[
(x, z) = \sum_{\xi \in \{0, 1\}^n} \lambda(\xi) (\xi, \psi(\xi)). \qedhere
\]

For the particular case that the function \(\psi\) has the form \(\psi(x) = f(x) = \sum_{ij \in E} a_{ij} x_i x_j\), Theorem 5 yields the following interpretation for \(\text{cav}[f](x)\) and \(\text{vex}[f](x)\).

**Corollary 1.** For the bilinear function \(f(x)\), we have

\[
\text{vex}[f](x) = \min \left\{ \sum_{ij \in E} a_{ij} \mu(X_i \cap X_j) : X_i \in \mathcal{L}, \mu(X_i) = x_i \text{ for all } i \in [n] \right\},
\]

\[
\text{cav}[f](x) = \max \left\{ \sum_{ij \in E} a_{ij} \mu(X_i \cap X_j) : X_i \in \mathcal{L}, \mu(X_i) = x_i \text{ for all } i \in [n] \right\}.
\]
In particular, for a polytope $P \subseteq \mathbb{R}^{n(n+1)/2}$ with $P \subseteq X(f)$, we have $\pi[P] = X(f)$ if and only if for every $x \in [0,1]^n$, there exist $X_1, \ldots, X_n \in \mathcal{L}$ and $X'_1, \ldots, X'_n \in \mathcal{L}$ with $\mu(X_i) = \mu(X'_i) = x_i$ for all $i \in [n]$, and

$$\sum_{ij \in E} a_{ij} \mu(X_i \cap X_j) = \text{LB}_P[f](x), \quad \sum_{ij \in E} a_{ij} \mu(X'_i \cap X'_j) = \text{UB}_P[f](x).$$

Proof. We observe that

$$\sum_{\xi \in \{0,1\}^n} \mu \left( R_\xi(X_1, \ldots, X_n) \right) f(\xi) = \sum_{\xi \in \{0,1\}^n} \mu \left( R_\xi(X_1, \ldots, X_n) \right) \sum_{ij \in E} a_{ij} \xi_i \xi_j$$

$$= \sum_{ij \in E} a_{ij} \sum_{\xi \in \{0,1\}^n} \mu \left( R_\xi(X_1, \ldots, X_n) \right) \xi_i \xi_j$$

$$= \sum_{ij \in E} a_{ij} \sum_{\xi \in \{0,1\}^n : \xi_i \xi_j = 1} \mu \left( \{ t \in [0,1] : \{ k \in [n] : t \in X_k \} = \xi \} \right)$$

$$= \sum_{ij \in E} a_{ij} \mu \left( \bigcup_{\xi \in \{0,1\}^n : \xi_i = \xi_j = 1} \{ t \in [0,1] : \{ k \in [n] : t \in X_k \} = \xi \} \right)$$

$$= \sum_{ij \in E} a_{ij} \mu \left( X_i \cap X_j \right). \quad \Box$$

Example 2. We can use Corollary 1 to prove again that $X(f)$ for $f(x_1, x_2) = x_1 x_2$ is given by the McCormick inequalities. From

$$\mu(X_1 \cap X_2) \leq \min \{ \mu(X_1), \mu(X_2) \} = \min \{ x_1, x_2 \},$$

it follows that $\text{cav}[f](x) \leq \min \{ x_1, x_2 \}$, and with $X_1 = [0, x_1]$, $X_2 = [0, x_2]$ we see that this bound can be achieved for all $x_1, x_2 \in [0,1]$, and therefore the concave envelope is given by $x_3 \leq x_1$ and $x_3 \leq x_2$. Similarly, from

$$\mu(X_1 \cap X_2) \geq \max \{ 0, \mu(X_1) + \mu(X_2) - 1 \} = \max \{ 0, x_1 + x_2 - 1 \},$$

it follows that $\text{vex}[f](x) \geq \min \{ 0, x_1 + x_2 - 1 \}$, and with $X_1 = [0, x_1]$, $X_2 = [1 - x_2, 1]$ we see that this bound can be achieved for all $x_1, x_2 \in [0,1]$, and therefore the convex envelope is given by $x_3 \geq 0$ and $x_3 \geq x_1 + x_2 - 1$.

This example illustrates the use of Corollary 1 to characterize $X(f)$ in the simplest possible case, the function $f(x_1, x_2) = x_1 x_2$. It contains the main idea of the proofs of our main results presented in the next section. The difference is, that for more complicated functions the choice of the sets $X_i$ is not obvious, and can depend on the particular vector $x$ for which we want to find $\text{vex}[f](x)$.

Example 3. For $n = 5$ consider the function

$$f(x) = \sum_{1 \leq i < j \leq 5} x_i x_j,$$

corresponding to the graph shown on the left in Figure 3, and the point $x = (0.6, 0.3, 0.3, 0.9, 0.4)$. Corollary 1 can be used to verify that $\text{vex}[f](x) \leq 2$. For this purpose, consider the sets

$$X_1 = [0, 0.6), \quad X_2 = [0.6, 0.9), \quad X_3 = [0, 0.2) \cup [0.9, 1),$$

$$X_4 = [0, 0.1) \cup [0.2, 1), \quad X_5 = [0.1, 0.5),$$

illustrated on the right in Figure 3. There are six vectors $\xi$ with non-empty $R_\xi(X_1, \ldots, X_5)$:

$$R_{(1, 0, 1, 0, 1)}(X_1, \ldots, X_5) = [0, 0.1),$$

$$R_{(0, 1, 0, 1, 0)}(X_1, \ldots, X_5) = [0.1, 0.2),$$

$$R_{(1, 0, 0, 1, 1)}(X_1, \ldots, X_5) = [0.2, 0.5),$$

$$R_{(0, 0, 0, 1, 0)}(X_1, \ldots, X_5) = [0.5, 0.6),$$

$$R_{(0, 1, 0, 1, 0)}(X_1, \ldots, X_5) = [0.6, 0.9),$$

$$R_{(0, 0, 1, 1, 0)}(X_1, \ldots, X_5) = [0.9, 0.1).$$
So these sets \(X_1, \ldots, X_5\) correspond to the representation

\[
\begin{bmatrix}
0.6 & 1 & 0 & 0 & 0 \\
0.3 & 0 & 1 & 0 & 0 \\
0.3 & 0.1 & 1 & 0 & 0 \\
0.9 & 1 & 0 & 1 & 0 \\
0.4 & 1 & 1 & 1 & 0 \\
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
x_3 \\
x_4 \\
x_5 \\
\end{bmatrix}
\]

and extending this to the function value coordinate, we get

\[
\text{vex}[f](\mathbf{x}) \leq 0.1 f(1, 0, 1, 0, 1) + 0.1 f(1, 0, 1, 1, 0) + 0.3 f(1, 0, 1, 1, 1) + 0.1 f(1, 0, 0, 1, 0) + 0.3 f(0, 1, 0, 1, 0) + 0.1 f(0, 0, 1, 1, 0) = 0.3 + 0.3 + 0.9 + 0.1 + 0.3 + 0.1 = 2.
\]

The following result, which was proved in [LNL12] (see also [TRX12]), is an immediate consequence of Corollary 1.

**Corollary 2.** If all edges are positive, then \(\text{cav}[f](\mathbf{x}) = \sum_{i,j \in E} a_{ij} \min\{x_i, x_j\}\).

**Proof.** With \(X_i = [0, x_i]\) for all \(i \in [n]\), we get

\[
\text{cav}[f](\mathbf{x}) \geq \sum_{i,j \in E} a_{ij} \mu(X_i \cap X_j) = \sum_{i,j \in E} a_{ij} \mu([0, \min\{x_i, x_j\}]) = \sum_{i,j \in E} a_{ij} \min\{x_i, x_j\}.
\]

On the other hand, for any feasible choice of the sets \(X_i\), we have, for all \(i, j \in [n]\),

\[
\mu(X_i \cap X_j) \leq \min\{\mu(X_i), \mu(X_j)\} = \min\{x_i, x_j\}.
\]

With the assumption that \(a_{ij} > 0\) for all \(ij \in E\), this implies

\[
\text{cav}[f](\mathbf{x}) \leq \sum_{i,j \in E} a_{ij} \min\{x_i, x_j\}.
\]

As another consequence, we can combine convex hull characterizations of graphs of two bilinear functions if they share at most one variable.

**Corollary 3.** Let \(f : [0, 1]^k \to \mathbb{R}\) and \(g : [0, 1]^{n-k+1} \to \mathbb{R}\) be two bilinear functions given as

\[
f(\mathbf{x}) = \sum_{1 \leq i < j \leq k} a_{ij} x_i x_j, \quad g(\mathbf{x}) = \sum_{k \leq i < j \leq n} a_{ij} x_k x_j,
\]

so that \(f\) depends only on variables \(x_1, \ldots, x_k\), and \(g\) depends only on variables \(x_{k+1}, \ldots, x_n\). Let \(P, Q \subseteq [0, 1]^{(n+1)/2}\) be polytopes with \(\pi(f)(P) = X(f)\) and \(\pi(g)(Q) = X(g)\), such that \(P\) is described by inequalities involving only the variables \(x_1, \ldots, x_k\), and \(Q\) is described by inequalities involving only the variables \(x_{k+1}, \ldots, x_n\). Then \(\pi(f + g)(P \cap Q) = X(f + g)\).
Proof. Fix \( x \in [0, 1]^n \). By assumption and Corollary 1, there are sets \( X_1, \ldots, X_n \in \mathcal{L} \) with 
\[ \mu(X_i) = x_i \text{ for all } i \in [k], \text{ and sets } X'_1, \ldots, X'_n \in \mathcal{L} \text{ with } \mu(X'_i) = x_i \text{ for all } i \in [k, n], \text{ such that} \]
\[ \sum_{1 \leq i < j \leq k} a_{ij} \mu(X_i \cap X_j) = LB_P[f](x), \quad \sum_{k \leq i < j \leq n} a_{ij} \mu(X'_i \cap X'_j) = LB_Q[g](x). \]

Applying a measure preserving bijection \([0, 1) \to [0, 1)\) that maps \( \mathcal{L} \) to \( \mathcal{L}_1 \) and \( X'_k \to X'_k \), we can assume that \( X_k = X'_k \), and then the sets \( X_1, \ldots, X_{k-1}, X_k = X'_k, X'_{k+1}, \ldots, X'_n \) provide a certificate for \( vex[f + g](x) = LB_P[f + g](x) \):
\[ \sum_{1 \leq i < j \leq k} a_{ij} \mu(X_i \cap X_j) + \sum_{k \leq i < j \leq n} a_{ij} \mu(X'_i \cap X'_j) = LB_P[f](x) + LB_Q[g](x) = LB_{P \cap Q}[f + g](x). \]

The same argument works for \( cav[f + g](x) = UB_{P \cap Q}[f + g](x) \).

3.2. Alternative proof for cliques. In order to illustrate the utility of the geometric characterization of 0–1 polytopes in a simpler setting than what we have for our main results, we start with an alternative proof for the following result that was proved in [Rik97; She97].

**Theorem 6.** If \( G = K_n \) and all edge weights are equal to 1, then \( X(f) = \pi(f)(P) \) where \( P \subseteq [0, 1]^{n(n+1)/2} \) is the polytope described by the inequalities \( y_{ij} \leq x_i \) and \( y_{ij} \leq x_j \) for all \( ij \in E \), together with
\[ sx(V) - y(E) \leq s(s + 1)/2, \quad s = 1, \ldots, n - 1. \]

To be precise, the result from [Rik97; She97] is just one half of Theorem 6: in our notation it says that
\[ vex[f](x) = \max \left\{0, \max \left\{sx(V) - s(s + 1)/2 : s = 1, 2, \ldots, n - 1 \right\}\right\}. \]

The correspondence between this statement in the original space \( \mathbb{R}^{n+1} \) and our version in the extended space \( \mathbb{R}^{n(n+1)/2} \) comes from the fact that the only constraints enforcing lower bounds on the \( y \)-variables are (18), which put lower bounds on \( y(E) \) which is precisely the term corresponding to \( f(x) \) when the products \( x_i x_j \) are replaced by the variables \( y_{ij} \). The other half of Theorem 6 is an immediate consequence of Corollary 2: In order to describe \( cav[f](x) \) it is sufficient to require \( y_{ij} \leq \min \{x_i, x_j\} \) for all \( ij \in E \). In view of Corollaries 1 and 2, Theorem 6 is a consequence of the following lemma.

**Lemma 1.** For every \( x \in [0, 1]^n \),
\[ LB_P[f](x) = vex[f](x) = s(x_1 + \cdots + x_n) - \left(\frac{s + 1}{2}\right), \]
where \( s = |x_1 + \cdots + x_n| \).

**Proof.** Since \( vex[f](x) \geq LB_P[f](x) \) it is sufficient to show that
\[ vex[f](x) \leq s(x_1 + \cdots + x_n) - \left(\frac{s + 1}{2}\right), \quad (19) \]
\[ LB_P[f](x) \geq s(x_1 + \cdots + x_n) - \left(\frac{s + 1}{2}\right). \quad (20) \]

In order to show (19) using Corollary 1 we concatenate intervals of lengths \( x_1, \ldots, x_n \) and obtain sets \( X_i \subseteq [0, 1) \) by interpreting the result modulo \( \mathbb{Z} \). More formally, the sets \( X_i \) are defined as follows: for \( i = 1 \), put \( X_1 = [0, x_1) \). Now let \( i \geq 2 \), suppose \( X_{i-1} \) has been defined already, set \( b = \sup X_{i-1} \), and put
\[ X_i = \begin{cases} [b, b + x_i) & \text{if } b + x_i \leq 1, \\ [b, 1) \cup [0, x_i - (1 - b)) & \text{if } b + x_i > 1. \end{cases} \]

This construction is illustrated in Figure 4 where \( s = |2.5| = 2 \). Now \( [0, 1) = A \cup B \), where
\[ A = \{t \in [0, 1) : \{i \in [n] : t \in X_i\} = s\}, \quad B = \{t \in [0, 1) : \{i \in [n] : t \in X_i\} = s + 1\}, \]
and $\mu(B) = (x_1 + \cdots + x_n) - s$, $\mu(A) = s + 1 - (x_1 + \cdots + x_n)$. Therefore,

$$
\sum_{1 \leq i < j \leq n} \mu(X_i \cap X_j) = \left(\frac{s}{2}\right) \mu(A) + \left(\frac{s + 1}{2}\right) \mu(B) \\
= \left(\frac{s}{2}\right) [s + 1 - (x_1 + \cdots + x_n)] + \left(\frac{s + 1}{2}\right) [(x_1 + \cdots + x_n) - s] \\
= (x_1 + \cdots + x_n) \left(\frac{s + 1}{2} - \frac{s}{2}\right) + (s + 1) \left(\frac{s}{2}\right) - s \left(\frac{s + 1}{2}\right) \\
= s(x_1 + \cdots + x_n) - \left(\frac{s + 1}{2}\right),
$$

and this implies (19). If $s < n - 1$ then (20) is obvious: for $s = 0$ the right-hand side is zero, and for $1 \leq s \leq n - 1$,

$$
\sum_{1 \leq i < j \leq n} y_{ij} \geq s(x_1 + \cdots + x_n) - \left(\frac{s + 1}{2}\right)
$$

is one of the clique inequalities. Finally, if $s = n$ then

$$
\sum_{1 \leq i < j \leq n} y_{ij} = \left(\frac{n}{2}\right) = n^2 - \left(\frac{n + 1}{2}\right) = n(x_1 + \cdots + x_n) - \left(\frac{n + 1}{2}\right).
$$

## 4. Proofs of Main Results

In Sections 4.1 and 4.2 we will use Corollary 1 to prove Theorems 1 and 2.

### 4.1. Proof of Theorem 1

We will establish this result by proving $\text{vex}([f](\mathbf{x})) \leq \text{LB}_P[f](\mathbf{x})$. Without loss of generality we assume $x_n \leq x_{n-1}$ and $x_2 \geq \cdots \geq x_{n-2}$, and we proceed as follows. We start with $X_n = [0, x_n)$ and $X_{n-1} = [0, x_{n-1})$ and construct the sets $X_1, \ldots, X_{n-2}$ as described in Algorithm 1.

#### Example 4

For $n = 6$ two different outcomes of Algorithm 1 are illustrated in Figure 5: For $\mathbf{x} = (0.9, 0.6, 0.2, 0.1, 0.6, 0.4)$ the algorithm terminates with $b = 1$, while for $\mathbf{x} = (0.9, 0.8, 0.2, 0.1, 0.6, 0.4)$, we have still $b < 1$ in the end.

Setting $y_{ij} = \mu(X_i \cap X_j)$ for all $ij \in E$, Corollary 1 implies $\text{vex}([f](\mathbf{x})) \leq \sum_{ij \in E} y_{ij}$, and it is sufficient to show that $\mathbf{y}$ is an optimal solution for the LP defining $\text{LB}_P[f](\mathbf{x})$:

Minimize $\sum_{ij \in E} y_{ij}$ subject to the McCormick inequalities (2) and (10)–(11).
In other words, we need to verify the inequalities listed in Theorem 1 imply that this expression is a lower bound for $\text{LB}_P(x)$. In other words, we need to verify $\sum_{ij \in E} y_{ij} \leq \sum_{ij \in E} y'_{ij}$ for every $y'$ with $(x, y') \in P$. The following observations turn out to be useful.

- During the runtime of the algorithm the parameter $b$ is never decreasing.
- After every step of Algorithm 1 there is an integer $s$ such that
  \[
  \left| \{ i \in [n] : t \in X_i \} \right| = \begin{cases} 
    s + 2 & \text{for } t < a, \\
    s + 1 & \text{for } a \leq t < b, \\
    s & \text{for } b \leq t < 1
  \end{cases}
  \]
  if $b < 1$, and
  \[
  \left| \{ i \in [n] : t \in X_i \} \right| = \begin{cases} 
    s + 1 & \text{for } t < a, \\
    s & \text{for } a \leq t < 1
  \end{cases}
  \]
  if $b = 1$.

- If $b = 1$ at termination of the algorithm, and $s$ is the integer with $\left| \{ i \in [n] : t \in X_i \} \right| = s$ for $t \in [a, 1]$ then $a = x_1 + x_2 + \cdots + x_n - s$.
- If $b < 1$ at termination of the algorithm, and $s$ is the integer with $\left| \{ i \in [n] : t \in X_i \} \right| = s$ for $t \in [b, 1]$ then $a = x_1 + x_2 + \cdots + x_b + x_2 + \cdots + x_n - s$ and $b = \frac{x_{s+1} + x_{s+2} + \cdots + x_{n-1}}{2}$.

**Case 1:** $b = 1$. Then $1 \leq s \leq n - 1$. As in the proof of Lemma 1,
\[
\sum_{ij \in E} y_{ij} = \sum_{1 \leq i < j \leq n} y_{ij} - y_{n-1, n} = s(x_1 + \cdots + x_n) - x_n - \binom{s + 1}{2}.
\]
For $s \leq n - 2$, we use (11):
\[
s(x_1 + \cdots + x_n) - x_n - \binom{s + 1}{2} \leq sx(V) - y'_{n,n-1} - \binom{s + 1}{2} \leq y'_{ij}(E).
\]
For $s = n - 1$, we combine (9) and (10):

$$y'(E) = \left[ y'(E(V \setminus \{n - 1, n\})) + \frac{1}{2} \sum_{i=1}^{n-2} (y_{i,n-1} + y_{in}') \right] + \frac{1}{2} \sum_{i=1}^{n-2} (y_{i,n-1} + y_{in}')$$

$$\geq (n - 2) \left[ x(V \setminus \{n - 1, n\}) + \frac{x_{n-1} + x_n}{2} \right] - \left( \frac{n - 1}{2} \right)$$

$$+ x(V \setminus \{n - 1, n\}) + \frac{(n - 2)(x_{n-1} + x_n)}{2} - (n - 2)$$

$$= (n - 1)x(V) - (x_{n-1} + x_n) - \left( \frac{n}{2} \right) + 1 \geq (n - 1)x(V) - x_n - \left( \frac{n}{2} \right),$$

as required.

**Case 2:** $b < 1$. Then $0 \leq s \leq n - 2$, and

$$\sum_{ij \in E} y_{ij} = a \left( \frac{s + 2}{2} \right) - 1 + (x_n - a) \left( \frac{s + 1}{2} \right) - 1 + (b - x_n) \left( \frac{s + 1}{2} \right) + (1 - b) \left( \frac{s}{2} \right)$$

$$= a(s + 1) - x_n + bs + \left( \frac{s}{2} \right)$$

$$= (s + 1)x(V) + (x_1 + \cdots + x_s + x_{n-s}) - \left( \frac{s + 1}{2} \right)$$

$$= s \left( x(V \setminus \{n - 1, n\}) + \frac{x_{n-1} + x_n}{2} \right) + \frac{1}{2} \sum_{i=1}^{s} (2x_i + x_{n-1} + x_n - 2) - \left( \frac{s + 1}{2} \right).$$

Next we verify that this is a lower bound for $\text{LB}_P[f(x)]$. We start with the inequality

$$\sum_{ij \in E} y_{ij}' = \sum_{ij \in E(V \setminus \{n-1,n\})} y_{ij}' + \sum_{i=1}^{n-2} (y_{i,n-1} + y_{in}')$$

$$\geq \left[ \sum_{ij \in E(V \setminus \{n-1,n\})} y_{ij}' \right] + \frac{1}{2} \sum_{i=1}^{n-2} (y_{i,n-1} + y_{in}')$$

$$\quad + \frac{1}{2} \sum_{i=1}^{s} (y_{i,n-1} + y_{in}').$$

We use (9) and (10) to bound the second and the first part, respectively:

$$\sum_{ij \in E(V \setminus \{n-1,n\})} y_{ij}' \geq \frac{1}{2} \sum_{i=1}^{n-2} (y_{i,n-1} + y_{in}') \geq s \left( x(V \setminus \{n-1,n\}) + \frac{x_{n-1} + x_n}{2} \right) - \left( \frac{s + 1}{2} \right),$$

$$\frac{1}{2} \sum_{i=1}^{s} (y_{i,n-1} + y_{in}') \geq \frac{1}{2} \sum_{i=1}^{s} (2x_i + x_{n-1} + x_n - 2),$$

and as a consequence $y'(E) \geq y(E)$, as required.

The second part of the theorem (that $P$ is a minimal extension of $X(f)$) is proved by identifying, for each inequality listed in Theorem 1, a point $(x, y)$ which is contained in the polytope $P'$ obtained from $P$ by omitting the inequality, such that $\pi [f(x, y)] \not\in X(f)$. This is described in detail in Appendix A.

### 4.2. Proof of Theorem 2

Throughout all indices are in $[n]$ and have to be read modulo $n$ in the obvious way. In particular, $n \equiv 0$ and $n + 1 \equiv 1$. The $n$-cycle corresponds to the function

$$f(x) = \sum_{i=1}^{n} a_i x_i x_{i+1},$$
where \( a \) is arbitrary with \( a_i \neq 0 \) for all \( i \in [n] \). Let \( P \subseteq [0,1]^{2n} \) be the polytope described by the McCormick inequalities together with (12) and (13). We claim that \( \pi[f](P) = X(f) \), and that (12) (resp. (13)) can be omitted if \( |E^-| \) (resp. \( |E^+| \)) is even.

We need to show that for every \( \mathbf{x} \in [0,1]^n \) we have \( \text{vex}[f](\mathbf{x}) = \text{UB}_P[f](\mathbf{x}) \) and \( \text{cav}[f](\mathbf{x}) = \text{UB}_P[f](\mathbf{x}) \). We present the argument for \( \text{cav}[f](\mathbf{x}) = \text{UB}_P[f](\mathbf{x}) \) in detail, as \( \text{vex}[f](\mathbf{x}) = \text{UB}_P[f](\mathbf{x}) \) can be proved similarly. Fix \( \mathbf{x} \in [0,1]^n \) and put

\[
\mu_i = \min \{x_i, x_{i+1}\}, \\
\eta_i = \max \{0, x_i + x_{i+1} - 1\}, \\
A = x(V^+) - x(V^-) + \left\lfloor \frac{|E^-|}{2} \right\rfloor.
\]

Then

\[
\text{UB}_P[f](\mathbf{x}) = \max \left\{ \sum_{i=1}^{n} a_i y_i : \eta_i \leq y_i \leq \mu_i, \ y(E^+) - y(E^-) \leq A \right\}
\]

\[
= \min \left\{ \sum_{i=1}^{n} (\mu_i z_i - \eta_i w_i) + A \alpha : \ z_i - w_i + \alpha \geq a_i \text{ for } i \in E^+, \\
\quad z_i - w_i - \alpha \geq a_i \text{ for } i \in E^-, \ z_i, w_i, \alpha \geq 0 \right\}.
\]

W.l.o.g. we assume \( |a_n| \leq |a_i| \) for all \( i \in [n] \), and we define sets \( X_i \subseteq [0,1] \) as follows. Let \( X_1 = [0, x_1) \) and

\[
X_2 = \begin{cases} 
[0, x_2) & \text{if } a_1 > 0, \\
[1 - x_2, 1) & \text{if } a_1 < 0.
\end{cases}
\]

For \( i \geq 3 \) we set \( E_i^- = \{ j : i \leq j \leq n, a_j < 0 \} \) and define \( X_i \) depending on the parity of \( |E_i^-| \) and the sign of \( a_{i-1} \). Intuitively, we can think of filling a bucket of capacity \( x_i \) from the reservoirs \( R_1 = X_i \setminus X_1, R_2 = X_i \setminus X_1 \cap X_1, R_3 = [0,1) \setminus (X_1 \cup X_i-1) \) and \( R_4 = X_i \setminus X_i-1 \), and there are two objectives:

1. If \( a_{i-1} > 0 \) we want to maximize \( \mu(X_{i-1} \cap X_i) \), so the reservoirs \( R_1 \) and \( R_2 \) are used before \( R_3 \) and \( R_4 \). If \( a_{i-1} < 0 \) then we want to minimize \( \mu(X_{i-1} \cap X_i) \), so \( R_3 \) and \( R_4 \) are used before \( R_1 \) and \( R_2 \).
2. If \( |E_i^-| \) is odd we want to minimize \( \mu(X_i \cap X_i) \), so \( R_1 \) is used before \( R_2 \) and \( R_3 \) before \( R_4 \). If \( |E_i^-| \) is even we want to maximize \( \mu(X_i \cap X_i) \), so \( R_2 \) is used before \( R_1 \) and \( R_4 \) before \( R_3 \).

**Algorithm 2** \textbf{Bucket}(\( Y_1, Y_2, Y_3, Y_4, x \))

\textbf{Input:} A partition \( [0,1] = Y_1 \cup Y_2 \cup Y_3 \cup Y_4 \) (with \( Y_k \in \mathcal{L} \)) and capacity \( x \in [0,1] \)

Initialize \( X \leftarrow \emptyset \) and \( k \leftarrow 1 \)

\textbf{while} \( \mu(X) < x \) \textbf{do}

- Let \( Z \in \mathcal{L} \) be a subset of \( Y_k \) with \( \mu(Z) = \min \{ \mu(Y_k), x - \mu(X) \} \)
- \( X \leftarrow X \cup Z \)
- \( k \leftarrow k + 1 \)

\textbf{Output:} \( X \in \mathcal{L} \) with \( \mu(X) = x \)

More formally, \( X_i = \begin{cases} 
\text{Bucket}(R_1, R_2, R_3, R_4, x_i) & \text{if } a_{i-1} > 0 \text{ and } |E_i^-| \text{ odd,} \\
\text{Bucket}(R_2, R_1, R_4, R_3, x_i) & \text{if } a_{i-1} > 0 \text{ and } |E_i^-| \text{ even,} \\
\text{Bucket}(R_3, R_4, R_1, R_2, x_i) & \text{if } a_{i-1} < 0 \text{ and } |E_i^-| \text{ odd,} \\
\text{Bucket}(R_4, R_3, R_2, R_1, x_i) & \text{if } a_{i-1} < 0 \text{ and } |E_i^-| \text{ even.}
\end{cases} \)
where the function \textbf{Bucket} is described in Algorithm 2. Note that this corresponds to a solution with

\[ y_i = \mu(X_i \cap X_{i+1}) = \begin{cases} 
\mu_i & \text{for } i \in E^+ \setminus \{n\}, \\
\eta_i & \text{for } i \in E^- \setminus \{n\}.
\end{cases} \]

\[ x_1 = 0.6 \]
\[ x_2 = 0.5 \]
\[ x_3 = 0.3 \]
\[ x_4 = 0.5 \]
\[ x_5 = 0.4 \]
\[ x_6 = 0.6 \]
\[ x_7 = 0.5 \]
\[ x_8 = 0.6 \]

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure6.png}
\caption{Constructing the sets \( X_i \), where the edge labels indicate the sign of the coefficient \( a_i \).}
\end{figure}

**Example 5.** The construction is illustrated in Figure 6, and with \(|a_i| = 1\) for all \( i \in [8] \) the corresponding objective value is 2.3 and we conclude \( \text{cav}[f](x) = \text{UB}_P[f](x) = 2.3 \) because (12) becomes

\[ x(V^-) - x(V^+) + y(E^+) - y(E^-) = 0.4 - 1.7 + f(x) \leq \left\lfloor \frac{|E^-|}{2} \right\rfloor = 1. \]

Next we define the defects

\[ \delta_i = \begin{cases} 
\mu(X_i \cap X_i) - \max\{0, x_1 + x_i - 1\} & \text{if } |E_i^-| \text{ is odd}, \\
\min\{x_1, x_i\} - \mu(X_i \cap X_i) & \text{if } |E_i^-| \text{ is even}.
\end{cases} \]

We have \( \delta_i \geq 0 \) for all \( i \in [n] \) and

\[ \text{cav}[f](x) \geq \sum_{i=1}^{n} a_i \mu(X_i \cap X_{i+1}) = \sum_{i \in E^+} a_i \mu_i + \sum_{i \in E^-} a_i \eta_i - |a_n| \delta_n, \]

so in order to complete the proof of the claim \( \text{cav}[f](x) = \text{UB}_P[f](x) \) it is sufficient to prove

\[ \text{UB}_P[f](x) \leq \sum_{i \in E^+} a_i \mu_i + \sum_{i \in E^-} a_i \eta_i - |a_n| \delta_n. \] (23)

If \( \delta_n = 0 \) then this follows immediately from the McCormick inequalities which imply

\[ a_i \eta_i \leq \begin{cases} 
\mu_i & \text{for } i \in E^+, \\
\eta_i & \text{for } i \in E^-.
\end{cases} \]

For \( \delta_n > 0 \) the claim is a consequence of the following lemma.

**Lemma 2.** If \( \delta_n > 0 \) then \( \delta_n = \sum_{i \in E^+} \mu_i - \sum_{i \in E^-} \eta_i - A. \)
Using Lemma 2, we can prove inequality (23) by LP duality. If \( a_n > 0 \) we define a solution for the dual problem (22) by \( \alpha = a_n \) and (using the assumption that \( |a_n| \leq |a_i| \) for all \( i \in [n] \))

\[
    z_i = \begin{cases} 
    a_i - a_n & \text{for } i \in E^+ , \\
    0 & \text{for } i \in E^- , 
    \end{cases} \\
    w_i = \begin{cases} 
    0 & \text{for } i \in E^+ , \\
    -a_i - a_n & \text{for } i \in E^- . 
    \end{cases}
\]

This is a feasible solution for (22) with objective value

\[
    \sum_{i \in E^+} \mu_i (a_i - a_n) + \sum_{i \in E^-} \eta_i (a_i + a_n) + Aa_n = \sum_{i \in E^+} a_i \mu_i + \sum_{i \in E^-} a_i \eta_i + A \left( \sum_{i \in E^+} \mu_i + \sum_{i \in E^-} \eta_i \right) = \sum_{i \in E^+} a_i \mu_i + \sum_{i \in E^-} a_i \eta_i - a_n \delta_n .
\]

Similarly, for \( a_n < 0 \) we define a solution for the dual problem (22) by \( \alpha = -a_n \) and

\[
    z_i = \begin{cases} 
    a_i + a_n & \text{for } i \in E^+ , \\
    0 & \text{for } i \in E^- , 
    \end{cases} \\
    w_i = \begin{cases} 
    0 & \text{for } i \in E^+ , \\
    a_n - a_i & \text{for } i \in E^- . 
    \end{cases}
\]

with objective value

\[
    \sum_{i \in E^+} \mu_i (a_i + a_n) + \sum_{i \in E^-} \eta_i (a_i - a_n) - Aa_n = \sum_{i \in E^+} a_i \mu_i + \sum_{i \in E^-} a_i \eta_i + A \left( \sum_{i \in E^+} \mu_i - \sum_{i \in E^-} \eta_i - A \right) = \sum_{i \in E^+} a_i \mu_i + \sum_{i \in E^-} a_i \eta_i + a_n \delta_n .
\]

Before proving Lemma 2 we show that the sequence \( (\delta_i)_{i=2,...,n} \) is decreasing, and therefore in the proof of Lemma 2 we may assume \( \delta_i > 0 \) for all \( i \in [n] \).

**Lemma 3.** For all \( i \in \{3, \ldots, n\} \) we have \( \delta_i \leq \delta_{i-1} \).

**Proof.** We check the following implications.

1. \( |E_{i-1}| \) odd, \( a_{i-1} > 0 \) \( \implies \) \( \delta_i = \delta_{i-1} \)
   \[ \begin{cases} 
   \max\{0, x_{i-1} - x_i, (x_1 + x_i - 1)\} & \text{if } x_1 + x_{i-1} \leq 1, \\
   \max\{0, 1 - x_1 - x_i, x_i - x_{i-1}\} & \text{if } x_1 + x_{i-1} \geq 1 . 
   \end{cases} \]

2. \( |E_{i-1}| \) odd, \( a_{i-1} < 0 \) \( \implies \) \( \delta_i = \delta_{i-1} \)
   \[ \begin{cases} 
   \max\{0, x_1 - x_i, (x_{i-1} + x_i - 1)\} & \text{if } x_1 + x_{i-1} \leq 1, \\
   \max\{0, 1 - x_{i-1} - x_i, x_i - x_1\} & \text{if } x_1 + x_{i-1} \geq 1 . 
   \end{cases} \]

3. \( |E_{i-1}| \) even, \( a_{i-1} > 0 \) \( \implies \) \( \delta_i = \delta_{i-1} \)
   \[ \begin{cases} 
   \max\{0, x_{i-1} - x_i, (x_i - 1)\} & \text{if } x_{i-1} \leq x_1, \\
   \max\{0, x_1 - x_i, x_i - x_{i-1}\} & \text{if } x_{i-1} \geq x_1 . 
   \end{cases} \]

4. \( |E_{i-1}| \) even, \( a_{i-1} < 0 \) \( \implies \) \( \delta_i = \delta_{i-1} \)
   \[ \begin{cases} 
   \max\{0, 1 - x_1 - x_i, x_i - x_{i-1} + 1\} & \text{if } x_{i-1} \leq x_1, \\
   \max\{0, 1 - x_{i-1} - x_i, x_i + x_1 - 1\} & \text{if } x_{i-1} \geq x_1 . 
   \end{cases} \]

**Proof of Lemma 2.** If \( |E^-| \) is even then \( \delta_2 = 0 \), hence \( \delta_i = 0 \) for all \( i \in [2, n] \) by Lemma 3, and there is nothing to do. For odd \( |E^-| \) we proceed by induction on \( n \). Note that the construction of the sets \( X_i \), the definition of the numbers \( \delta_i \), and the statement of the lemma depend only on sequences \( (x_1, \ldots, x_n) \) and \( (a_1, \ldots, a_n) \) (actually only on the signs of the \( a_i \)). Therefore we can use \( n = 2 \) as the base case. Then \( |E^-| = 1, V^+ = V^- = \emptyset, A = 0 \), and we have the following two cases.

**Case 1:** if \( a_2 < 0 < a_1 \), then \( \mu(X_1 \cap X_2) = \min\{x_1, x_2\} \) and

\[
    \delta_2 = \mu(X_1 \cap X_2) - \max\{0, x_1 + x_2 - 1\} = \mu_1 - \eta_2 .
\]

**Case 2:** if \( a_1 < 0 < a_2 \), then \( \mu(X_1 \cap X_2) = \max\{0, x_1 + x_2 - 1\} \) and

\[
    \delta_2 = \min\{x_1, x_2\} - \mu(X_1 \cap X_2) = \mu_2 - \eta_1 .
\]
Now let \( n \geq 3 \) and set
\[
\gamma = \sum_{i \in E^+} \mu_i - \sum_{i \in E^-} \eta_i - A = \sum_{i \in E^+} \mu_i - \sum_{i \in E^-} \eta_i - x(V^+) + x(V^-) - \left[ \frac{|E^-|}{2} \right],
\]
so that our aim becomes to show \( \delta_n = \gamma \). Applying the induction hypothesis to the sets \( X_1, \ldots, X_{n-1} \) that are obtained by applying the construction for the sequences \((x_1, \ldots, x_{n-1})\) and \((a_1, \ldots, a_{n-2}, \text{sign}(a_{n-1}a_n))\) (the number of negative terms is still odd), we get
\[
\delta_{n-1} = \begin{cases} 
\gamma - \mu_n + x_n + \min\{x_{n-1}, x_1\} & \text{if } n - 1, n \in E^+ , \\
\gamma + \eta_n - x_n - x_{n-1} - 1 + \min\{x_{n-1}, x_1\} + 1 & \text{if } n - 1, n \in E^- , \\
\gamma - \mu_{n-1} + \eta_{n-1} + x_n - \max\{0, x_{n-1} + x_1 - 1\} & \text{if } n - 1 \in E^+ , n \in E^- , \\
\gamma + \eta_{n-1} - \mu_n + x_1 - \max\{0, x_{n-1} + x_1 - 1\} & \text{if } n - 1 \in E^- , n \in E^+ .
\end{cases}
\]

Now we discuss the four cases separately. The detailed case analysis can be found in Appendix B.

**Case 1:** \( n - 1, n \in E^+ \). We may assume \( \mu(X_1 \cap X_{n-1}) < x_n < x_1 + x_{n-1} - \mu(X_1 \cap X_{n-1}) \) since otherwise \( \delta_n = 0 \).

- **Case 1.1:** \( x_{n-1} \leq x_1 \). In this case \( \delta_{n-1} = \mu(X_{n-1} \setminus X_1) \).
- **Case 1.2:** \( x_{n-1} > x_1 \). In this case \( \delta_{n-1} = \mu(X_1 \setminus X_{n-1}) \).

**Case 2:** \( n - 1, n \in E^- \). We may assume \( 1 - \mu(X_1 \cup X_{n-1}) < x_n < 1 - \mu(X_1 \cap X_{n-1}) \) since otherwise \( \delta_n = 0 \).

- **Case 2.1:** \( x_{n-1} \leq x_1 \). In this case \( \delta_{n-1} = \mu(X_{n-1} \setminus X_1) = \mu(X_1 \cup X_{n-1}) - x_1 \).
- **Case 2.2:** \( x_{n-1} > x_1 \). In this case \( \delta_{n-1} = \mu(X_1 \setminus X_{n-1}) = \mu(X_1 \cup X_{n-1}) - x_{n-1} \).

**Case 3:** \( n - 1 \in E^+, n \in E^- \). We may assume \( \mu(X_{n-1} \setminus X_1) < x_n < 1 - \mu(X_1 \cap X_{n-1}) \) since otherwise \( \delta_n = 0 \).

- **Case 3.1:** \( x_1 + x_{n-1} \leq 1 \). In this case \( \delta_{n-1} = \mu(X_1 \cap X_{n-1}) \).
- **Case 3.2:** \( x_1 + x_{n-1} > 1 \). In this case \( \delta_{n-1} = \mu([0, 1) \setminus (X_1 \cup X_{n-1})) \).

**Case 4:** \( n - 1 \in E^-, n \in E^+ \). We may assume \( \mu(X_{n-1} \setminus X_1) < x_n < 1 - \mu(X_1 \setminus X_{n-1}) \) since otherwise \( \delta_n = 0 \).

- **Case 4.1:** \( x_1 + x_{n-1} \leq 1 \). In this case \( \delta_{n-1} = \mu(X_1 \cap X_{n-1}) \).
- **Case 4.2:** \( x_1 + x_{n-1} > 1 \). In this case \( \delta_{n-1} = \mu([0, 1) \setminus (X_1 \cup X_{n-1})) \).

Finally, to complete our proof of Theorem 2, we need to verify necessity of the McCormick inequalities (2) and the inequalities (12) and (13). For each of these inequalities, we exhibit a point \((x, y) \in P'\), where \(P'\) is the polytope obtained by dropping an inequality from \(P\), such that \(\pi(f)(x, y) \not\in X(f)\).

The inequality \( y_i \leq x_i \). Let \( x_{i+1} = 1 \) and \( x_j = 0 \) for all \( j \in [n] \setminus \{i + 1\} \), so that \((x, z) \in X(f) \iff z = 0\). Setting \( y_1 = 1 \) and \( y_j = 0 \) for all \( j \in [n] \setminus \{i\} \), we obtain a point \((x, y)\) with \(\pi(f)(x, y) = (x, a_i) \not\in X(f)\). If \(E^- \neq \{i + 1\}\) and \(E^+ \neq \{i + 1\}\), then \((x, y)\) satisfies (12) and (13), so \((x, y) \in P'\), as required. But if \(E^- = \{i + 1\}\) (resp. \(E^+ = \{i + 1\}\)) then \((x, y)\) is cut off by (12) (resp. (13)). In these cases we use the point given by \( x_{i+1} = x_{i+2} = 1, x_j = 0 \) for all \( j \in [n] \setminus \{i + 1, i + 2\}, y_1 = y_{i+1} = 1 \) and \( y_j = 0 \) for all \( j \in [n] \setminus \{i, i + 1\} \) instead.

The inequality \( y_i \leq x_{i+1} \) can be treated similarly.

The inequality \( y_i \geq x_i + x_{i+1} - 1 \). Let \( x_i = x_{i+1} = 1 \) and \( x_j = 0 \) for all \( j \in [n] \setminus \{i, i + 1\} \), so that \((x, z) \in X(f) \iff z = a_i\). Setting \( y_1 = 0 \), we obtain a point \((x, y)\) with \(\pi(f)(x, y) = (x, 0) \not\in X(f)\). If \(E^- \neq \{i - 1, i, i + 1\}\) and \(E^+ \neq \{i - 1, i, i + 1\}\) then \((x, y) \in P'\) and we are done. Otherwise, we use the point given by \( x_i = x_{i+1} = x_{i+2} = 1, x_j = 0 \) for all \( j \in [n] \setminus \{i, i + 1, i + 2\} \), \( y_{i+1} = 1 \) and \( y_j = 0 \) for all \( j \in [n] \setminus \{i + 1\} \).

The inequality (12). This is Padberg’s cycle inequality corresponding to the subset \( D = E^- \), and hence is known to be implied by the McCormick inequalities when \(|E^-|\) is even. Now let \(|E^-|\) be odd, say \(|E^-| = 2k + 1\) for some non-negative integer \(k\). Set \( x_i = 1/2 \) for all \( i \in [n] \).
Then \((x, y) \in P\) implies
\[
g(E^+) - y(E^-) \leq x(V^+) - x(V^-) + k = \frac{|V^+| - |V^-|}{2} + k = \frac{n - 2(2k + 1) + k}{2} = \frac{n - 2k - 2}{2} = \frac{|E^+| - 1}{2},
\]
and consequently, for every \((x, z) \in X(f)\),
\[
z = \sum_{i=1}^{n} a_i y_i = \sum_{i \in E^+} a_i y_i + \sum_{i \in E^-} a_i y_i < \frac{1}{2} \sum_{i \in E^+} a_i.
\]
Setting \(y_i = 1/2\) for all \(i \in E^+\) and \(y_i = 0\) for all \(i \in E^-\), we obtain a point \((x, y) \in P''\) with \(\pi[f](x, y) = \left(x, \frac{1}{2} \sum_{i \in E^+} a_i\right) \notin X(f)\).

The inequality (13). The arguments here are similar to those for (12).

4.3. **Proof of Theorem 3.** Let \(G = (V, E)\) be a cactus graph with \(k\) cycles and arbitrary edge weights. We want to show that for the corresponding function \(f, X(f) = \pi[f](P)\) where \(P\) is described by the McCormick inequalities and at most \(2k\) cycle inequalities. We prove this by induction on \(k\), the number of cycles. For \(k = 0\), \(G\) is a tree, and the McCormick inequalities are sufficient. For \(k = 1\), we proceed by induction on the number of edges that are not contained in the cycle. If there are no such edges then \(G\) is a cycle, and the claim follows from Theorem 2. Otherwise, there are two graphs \(G_1 = (V_1, E_1)\) and \(G_2 = (V_2, E_2)\) with \(V_1 \cup V_2 = V, E_1 \cup E_2 = E, |V_1 \cap V_2| = 1, E_2 \neq \emptyset\), and such that the cycle of \(G\) is contained in \(G_1\). Let \(f_1\) and \(f_2\) be the bilinear functions corresponding to the graphs \(G_1\) and \(G_2\), respectively. Since \(G_2\) is cycle-free, \(X(f_2)\) is described by the McCormick inequalities, and by induction, \(X(f_1)\) is described by the McCormick inequalities and at most two cycle inequalities. Now the result follows from Corollary 3. For \(k \geq 2\), there are two graphs \(G_1 = (V_1, E_1)\) and \(G_2 = (V_2, E_2)\) with \(V_1 \cup V_2 = V, E_1 \cup E_2 = E, |V_1 \cap V_2| = 1, k = k_1 + k_2\) where \(k_i (i \in \{1, 2\})\) is the number of cycles in graph \(G_i\). Again, let \(f_1\) and \(f_2\) be the bilinear functions corresponding to the graphs \(G_1\) and \(G_2\), respectively. By induction, \(X(f_1)\) is described by the McCormick inequalities and at most \(2k_1\) cycle inequalities, and \(X(f_2)\) is described by the McCormick inequalities and at most \(2k_2\) cycle inequalities. The result follows from Corollary 3.

5. **Conclusion and open problems**

We have used an extension of Zuckerberg’s geometric method for characterizing convex hulls of subsets of the discrete \(n\)-cube to find extended formulations for the convex hulls of graphs of bilinear functions corresponding to almost complete graphs with unit weights and cactus graphs with arbitrary weights. We think that this approach can be used in more general situations, but additional insights are needed to avoid the tedious case discussions as in the proof of Theorem 2.

A natural next test case for the method is the class of wheels. A wheel \(W_{n-1}\) is the graph with vertex set \(V = \{1, \ldots, n\}\) for \(n \geq 5\), and edge set
\[
E = \{\{1, 2\}, \{2, 3\}, \ldots, \{n - 2, n - 1\}\} \cup \{\{i, n\} : 1 \leq i \leq n - 1\}.
\]
That is, \(W_{n-1}\) is the cycle \(C_{n-1}\) with spokes from the center vertex \(n\). Since \(W_{n-1}\) has a \(K_4\)-minor, we know that \(QP(W_{n-1})\) needs more than the cycle inequalities for its description. One extra facet-defining inequality for \(QP(W_{n-1})\) is
\[
\left\lfloor \frac{(n-1)}{2} \right\rfloor x_n + \sum_{i=1}^{n} x_i - y(E) \leq \left\lfloor \frac{(n-1)}{2} \right\rfloor. \tag{24}
\]
which can be argued by first principles. Another inequality comes from the cut polytope of a graph. Barahona and Mahjoub [BMS86] introduced \(CUT(G)\) as the convex hull of incidence vectors of the cuts in \(G\), and showed that for every odd bicycle wheel in \(G\), there is a corresponding facet-defining inequality for \(CUT(G)\). An odd bicycle wheel is the graph \(W_{n-1} + \{v\}\) for odd \(n - 1\), where \(G + \{v\}\) is the graph obtained from \(G\) by joining every vertex of \(G\) to a new vertex \(v\). When \(G = W_{n-1}\) and \(n - 1\) is odd, then \(G + \{n + 1\}\) is an odd bicycle wheel and we have
exactly one odd bicycle wheel inequality for $\text{CUT}(W_{n-1} + \{n + 1\})$. Mapping this inequality to $QP(W_{n-1})$ using the well-known linear bijection between $QP(G)$ and $\text{CUT}(G + \{v\})$ [Sim90] leads to the inequality
\[
\left(\frac{n}{2}\right)x_n + 2\sum_{i=1}^{n-1}x_i - y(E) \leq n - 1
\]  
(25)
defining a facet of $QP(W_{n-1})$ when $n$ is odd. When $n - 1 = 5$, the inequalities (24) and (25) are sufficient to convexify $f$.

**Observation** (5-wheel). If $G = W_5$ and all edge weights are equal to 1, then $X(f) = \pi[f](P)$ where $P$ is the polytope described by the McCormick inequalities (2) together with
\[
2x_6 + x_1 + \cdots + x_5 - y(E) \leq 2,
\]  
(26)
\[
3x_6 + 2(x_1 + \cdots + x_5) - y(E) \leq 5,
\]  
(27)
which are are exactly inequalities (24) and (25) for $n = 6$.

We conjecture that this observation extends to any wheel $W_{n-1}$ with $n \geq 6$, $n$ even.

The open question on wheel graphs can be extended to a richer family of graphs called Halin graphs which was introduced by Halin [Hal71]. A Halin graph is a planar graph obtained from a tree without vertices of degree 2 by adding a cycle through all the leaves. Thus, a wheel is the simplest kind of a Halin graph. The insights gained from generalizing the above observation on wheel graphs might be useful to characterizing a polytope that does not project onto $QP(G)$ yet has $X(f) = \pi[f](P)$ and is a minimal such extension of $X(f)$, when $G$ is a Halin graph.

**Acknowledgements.** The first author thanks Jon Lee for bringing cactus graphs to his attention during stimulating discussions at the Dagstuhl Seminar on Designing and Implementing Algorithms for Mixed-Integer Nonlinear Optimization held at Schloss Dagstuhl in February 2018.

Appendix A. Minimality proof for the polytope in Theorem 1

We want to show that each of the inequalities listed in Theorem 1 is necessary in the sense that omitting it leads to a polytope $P'$ with $\pi[f](P') \supseteq X(f)$.

A.1. The McCormick inequalities $y_{ij} \leq x_i$. Let $P'$ be the polytope obtained from $P$ by omitting the inequality $y_{i^*,j^*} \leq x_{i^*}$, and consider the point $x$ with $x_{i^*} = 0$ and $x_i = 1$ for all $i \in V \setminus \{i^*\}$. Then $(x, z) \in X(f)$ if and only if

$$z = |E(V \setminus \{i^*\})| = \begin{cases} \binom{n-1}{2} - 1 & \text{if } i^* \in V \setminus \{n-1,n\}, \\ \binom{n-2}{2} & \text{if } i^* \in \{n-1,n\}. \end{cases}$$

If $\{i^*,j^*\} \neq \{n-1,n\}$ then we obtain a point $(x, y) \in P'$ by setting $y_{ij} = 1$ for all $ij \in E(V \setminus \{i^*\})$, $y_{i^*,j^*} = 1$ and $y_{i^*j} = 0$ for $j \neq j^*$. Then $\pi[f](x, y) \not\subseteq X(f)$ because $y(E) = \binom{n-1}{2} + 1$. For $i^* = n-1$, $j^* = n$, we obtain $(x, y) \in P'$ by setting $y_{in} = 1$ and $y_{i,n-1} = 0$ for all $i \in V \setminus \{n-1,n\}$, $y_{n-1,n} = 1$, and $yi_j = 1 - 1/\binom{n-2}{2}$ for all $ij \in E(V \setminus \{n-1,n\})$. Then $\pi[f](x, y) \not\subseteq X(f)$ because

$$\sum_{ij \in E} y_{ij} = \binom{n-2}{2} - 1 + (n-2) = \binom{n-1}{2} - 1.$$

A.2. The inequalities (9). Without loss of generality, $i = 1$. We obtain a point $(x, y) \in P'$ by setting

$$x_{n-1} = x_n = y_{n-1,n} = 1/2, \quad x_1 = x_2 = y_{12} = 5/6, \quad x_3 = x_4 = \cdots = x_{n-2} = 0, \quad y_{1,n-1} = y_{1n} = 0, \quad y_{n-1,n} = y_{2n} = 1/2,$$

and $y_{ij} = 0$ for all remaining $ij \in E$. Then $\pi[f](x, y) = (x, 11/6) \not\subseteq X(f)$, because $(x, z) \in X(f)$ implies

$$z \geq (x_1 + x_2 - 1) + (x_1 + x_{n-1} - 1) + (x_1 + x_n - 1) + (x_2 + x_{n-1} - 1) + (x_2 + x_n - 1)$$

$$= 2/3 + 4(1/3) = 2.$$

A.3. The inequalities (10). Let $t \in [n-2]$, and consider the point $(x, y)$ given by

$$x_{n-1} = x_n = y_{n-1,n} = 1/2,$$

$$x_i = \begin{cases} 1 & \text{for } 1 \leq i \leq t, \\ 0 & \text{for } t+1 \leq i \leq n-2, \end{cases}$$

$$y_{i,n-1} = y_{i1} = \begin{cases} 1/2 & \text{for } 1 \leq i \leq t, \\ 0 & \text{for } t+1 \leq i \leq n-2, \end{cases}$$

$$y_{ij} = 1 - \frac{2}{l(t-1)} \quad \text{for } 1 \leq i < j \leq t,$$

and $y_{ij} = 0$ for all remaining $ij \in E$. Then $(x, y) \in P'$, where $P'$ is the polytope obtained from $P$ by omitting (10) for $s = t$, and $\pi[f](x, y) = (x, (t+1)/2) \not\subseteq X(f)$, because $(x, z) \in X(f)$ implies

$$z \geq \left(\frac{s}{2}\right) + s = \left(\frac{s+1}{2}\right).$$

A.4. The inequalities (11). The following lemma shows that (11) cannot be omitted for any $s < (n-1)/2$. 

Lemma 4. Let $t$ be an integer with $1 \leq t < (n-1)/2$, and consider the point $(x, y) \in \mathbb{R}^{n(n+1)/2}$ given by $x_{n-1} = 1$, $x_n = y_{n-1,n} = 0$,

$$
x_i = \frac{t-1/2}{n-2} \quad \text{for } 1 \leq i \leq n-2,
$$

$$
y_{i,n-1} = y_{i,n} = 0 \quad \text{for } i \leq n-2,
$$

$$
y_{ij} = \frac{t^2 - 1}{(n-2)(n-3)} \quad \text{for } 1 \leq i < j \leq n-2.
$$

Then $(x, y)$ satisfies all the constraints describing $P$ except (11) for $s = t$. Moreover,

$$
\pi[f](x, y) = \left( x, \frac{(t^2 - 1)/2}{n-2} \right) \notin X(f).
$$

Proof. All $y$-variables are non-negative so $y(E) \geq 0$. For the inequalities $y_{ij} \leq \min\{x_i, x_j\}$, we just need to check that

$$
\frac{t^2 - 1}{(n-2)(n-3)} \leq \frac{t - 1/2}{n-2},
$$

or equivalently, $\phi(t) \leq 0$ where $\phi$ is the quadratic function $\phi(t) = (t^2 - 1) - (t - 1/2)(n-3)$. This follows from $\phi(1) = (3-n)/2 < 0$ and $\phi((n-1)/2) = -(n-3)(n-5)/4 \leq 0$.

For (9), we use the assumption $2t < n-1$:

$$
2x_i + x_{n-1} + x_n - y_{n-1,n} - y_{in} = \frac{2t-1}{n-2} + 1 < 2.
$$

For (10), we use

$$
x(V \setminus \{n-1,n\}) + \frac{x_{n-1} + x_n}{2} = t,
$$

$$
y(E(V \setminus \{n-1,n\})) + \frac{1}{2} \sum_{i=1}^{n-2} (y_{i,n-1} + y_{in}) = \frac{t^2 - 1}{2}.
$$

Now (10) follows from

$$
st - \frac{t^2 - 1}{2} - \left( \frac{s + 1}{2} \right) = -\frac{1}{2} \left[ \frac{1}{2} \left( s - \frac{2t - 1}{2} \right)^2 + t - \frac{5}{4} \right] \leq 0
$$

for all integers $s$.

For (11), we have

$$
sx(V) - y(E) - y_{n-1,n} - \left( \frac{s + 1}{2} \right) = s \left( t + \frac{1}{2} \right) - \frac{t^2 - 1}{2} - \left( \frac{s + 1}{2} \right)
$$

$$
= -\frac{1}{2} (s - t + 1)(s - t - 1) \begin{cases} \leq 0 & \text{for } s \neq t, \\ \geq 1/2 & \text{for } s = t. \end{cases}
$$

Finally, $(x, (t^2 - 1)/2) \notin X(f)$ because

$$
tx(V) - z - x_n - \left( \frac{t + 1}{2} \right) = t \left( t + \frac{1}{2} \right) - \frac{t^2 - 1}{2} - \left( \frac{t + 1}{2} \right) = \frac{1}{2}
$$

while

$$
tx(V) - z - x_n - \left( \frac{t + 1}{2} \right) \leq 0
$$

is a valid inequality for $X(f)$. \hfill \Box

To conclude the proof, the next lemma shows that (11) cannot be omitted for any $s \geq (n-1)/2$. 

Lemma 5. Let $t$ be an integer with $(n - 1)/2 \leq t \leq n - 2$, and consider the point $(x, y) \in \mathbb{R}^{n(n+1)/2}$ given by $x_{n-1} = 1$, $x_n = y_{n-1,n} = 1/2$,

$$x_i = \frac{t - 1}{n - 2}$$

for $1 \leq i \leq n - 2$,

$$y_{i,n-1} = \frac{4t - n - 2}{3(n - 2)}$$ and $y_{i,n} = \frac{4t - n - 2}{6(n - 2)}$ for $i \leq n - 2$,

$$y_j = \frac{2t^2 - 8t + 2n + 1}{2(n - 2)(n - 3)}$$

for $1 \leq i < j \leq n - 2$.

Then $(x, y)$ satisfies all the constraints describing $P$ except (11) for $s = t$. Moreover,

$$\pi[f](x, y) = \left(x, \frac{2t^2 - 3}{4}\right) \notin X(f).$$

Proof. All $y$-variables are non-negative so $y(E) \geq 0$. For the inequalities $y_{ij} \leq \min\{x_i, x_j\}$, we need to check that

$$\frac{2t^2 - 8t + 2n + 1}{2(n - 2)(n - 3)} \leq \frac{t - 1}{n - 2},$$

$$\frac{4t - n - 2}{3(n - 2)} \leq \frac{t - 1}{n - 2}.$$

The first inequality is equivalent to $\phi(t) \leq 0$ where $\phi(t) = 2t^2 - 8t + 2n + 1 - 2(n - 3)(t - 1)$, and this follows from

$$\phi\left(\frac{n - 1}{2}\right) = -\frac{1}{2}(n^2 - 6n + 7) \leq 0, \quad \phi(n - 2) = 7 - 2n \leq 0.$$

The second inequality follows from $4t - n - 2 - 3(t - 1) = t + 1 - n < 0$.

For (9), we have

$$2x_i + x_{n-1} + x_n - y_{i,n-1} - y_{n,n} = \frac{2t - 2}{n - 2} + \frac{3}{2} - \frac{4t - n - 2}{2(n - 2)} = 2.$$

For (10), we use

$$x(V \setminus \{n - 1, n\}) + \frac{x_{n-1} + x_n}{2} = t - \frac{1}{4},$$

$$y(E(V \setminus \{n - 1, n\})) + \frac{1}{2} \sum_{i=1}^{n-2} (y_{i,n-1} + y_{n,n}) = \frac{2t^2 - 8t + 2n + 1}{4} + \frac{4t - n - 2}{4} = \frac{2t^2 - 4t + n - 1}{4}.$$

Now (10) follows from

$$s\left(t - \frac{1}{4}\right) = \frac{2t^2 - 4t + n - 1}{4} - \left(s + \frac{1}{2}\right) = -\frac{1}{2}\left[s - \frac{4t - 3}{4}\right]^2 + \frac{n-t}{2} - \frac{17}{16}$$

$$\leq -\frac{1}{2}\left[s - \frac{4t - 3}{4}\right]^2 - \frac{1}{16} \leq 0.$$

for all integers $s$.

For (11), we have

$$y(E) + y_{n,n-1} = \frac{2t^2 - 8t + 2n + 1}{4} + \frac{4t - n - 2}{2} + \frac{1}{2} = \frac{2t^2 - 1}{4},$$

and then

$$sx(V) - y(E) - y_{n-1,n} - \left(s + \frac{1}{2}\right) = s\left(t + \frac{1}{2}\right) = \frac{2t^2 - 1}{4} - \left(s + \frac{1}{2}\right)$$

$$= -\frac{1}{2}\left[(s-t)^2 - \frac{1}{2}\right] \leq 0 \quad \text{for } s \neq t,$$

$$= 1/4 \quad \text{for } s = t.$$
Finally, \((x, (2t^2 - 3)/4) \not\in X(f)\) because

\[
tx(V) - z - x_n - \left(\frac{t + 1}{2}\right) = t \left(\frac{t + 1}{2}\right) - \frac{2t^2 - 3}{4} - \left(\frac{t + 1}{2}\right) = \frac{3}{4}
\]

while

\[
\text{is a valid inequality for } X(f).
\]

\[\square\]

**Appendix B. Detailed case analysis in the proof of Lemma 2**

**Case 1:** \(n - 1, n \in E^+\). We may assume \(\mu(X_1 \cap X_{n-1}) < x_n < x_1 + x_{n-1} - \mu(X_1 \cap X_{n-1})\) since otherwise \(\delta_n = 0\).

**Case 1.1:** \(x_{n-1} \leq x_1\). In this case \(\delta_{n-1} = \mu(X_{n-1} \setminus X_1)\).

If \(x_n \leq x_{n-1}\) then

\[
\delta_n = \mu(X_n \setminus X_1) = \delta_{n-1} - (x_{n-1} - x_n)
\]

\[
= \gamma - \mu_{n-1} - \mu_n + x_n + \min\{x_{n-1}, x_1\} - (x_{n-1} - x_n)
\]

\[
= \gamma - x_n - x_n + x_n + x_{n-1} - (x_{n-1} - x_n) = \gamma.
\]

If \(x_{n-1} \leq x_n \leq x_1\) then

\[
\delta_n = \mu(X_n \setminus X_1) = \delta_{n-1}
\]

\[
= \gamma - \mu_{n-1} - \mu_n + x_n + \min\{x_{n-1}, x_1\}
\]

\[
= \gamma - x_n - x_n + x_n + x_{n-1} - (x_{n-1} - x_n) = \gamma.
\]

Finally, if \(x_n \geq x_1\) then

\[
\delta_n = \mu(X_n \setminus X_1) = \delta_{n-1} - (x_n - x_1)
\]

\[
= \gamma - \mu_{n-1} - \mu_n + x_n + \min\{x_{n-1}, x_1\} - (x_n - x_1)
\]

\[
= \gamma - x_n - x_n + x_n + x_{n-1} - (x_{n-1} - x_n) = \gamma.
\]

**Case 1.2:** \(x_{n-1} > x_1\). In this case \(\delta_{n-1} = \mu(X_1 \setminus X_{n-1})\).

If \(x_n \leq x_1\) then

\[
\delta_n = \mu(X_n \setminus X_1) = \delta_{n-1} - (x_1 - x_n)
\]

\[
= \gamma - \mu_{n-1} - \mu_n + x_n + \min\{x_{n-1}, x_1\} - (x_1 - x_n)
\]

\[
= \gamma - x_n - x_n + x_n + x_{n-1} - (x_{n-1} - x_n) = \gamma.
\]

If \(x_1 \leq x_n \leq x_{n-1}\) then

\[
\delta_n = \mu(X_1 \setminus X_n) = \delta_{n-1}
\]

\[
= \gamma - \mu_{n-1} - \mu_n + x_n + \min\{x_{n-1}, x_1\}
\]

\[
= \gamma - x_n - x_n + x_n + x_{n-1} = \gamma.
\]

Finally, if \(x_n \geq x_{n-1}\) then

\[
\delta_n = \mu(X_1 \setminus X_n) = \delta_{n-1} - (x_n - x_{n-1})
\]

\[
= \gamma - \mu_{n-1} - \mu_n + x_n + \min\{x_{n-1}, x_1\} - (x_n - x_{n-1})
\]

\[
= \gamma - x_n - x_n + x_n + x_{n-1} + 1 - (x_{n-1} - x_n) = \gamma.
\]

**Case 2:** \(n - 1, n \in E^-\). We may assume \(1 - \mu(X_1 \cup X_{n-1}) < x_n < 1 - \mu(X_1 \cap X_{n-1})\) since otherwise \(\delta_n = 0\).

**Case 2.1:** \(x_{n-1} \leq x_1\). In this case \(\delta_{n-1} = \mu(X_{n-1} \setminus X_1) = \mu(X_1 \cup X_{n-1}) - x_1\).

If \(x_n \leq 1 - x_1\) then

\[
\delta_n = \mu(X_n \cap X_1) = x_n - (1 - \mu(X_1 \cup X_{n-1})) = \delta_{n-1} - (1 - x_1 - x_n)
\]

\[
= \gamma + \eta_{n-1} + \eta_n - x_n - x_{n-1} - x_1 + \min\{x_{n-1}, x_1\} + 1 - (1 - x_1 - x_n)
\]

\[
= \gamma + 0 + 0 - x_n - x_{n-1} - x_1 + x_{n-1} + 1 - (1 - x_1 - x_n) = \gamma.
\]
If \(1 - x_1 \leq x_n \leq 1 - x_{n-1}\) then
\[
\delta_n = \mu([0, 1] \setminus (X_n \cup X_1)) = \mu(X_{n-1} \setminus X_1) = \delta_{n-1}
\]
\[
= \gamma + \eta_{n-1} + \eta_n - x_n - x_{n-1} - x_1 + \min\{x_{n-1}, x_1\} + 1
\]
\[
= \gamma + 0 + (x_n + x_1 - 1) - x_n - x_{n-1} - x_1 + x_{n-1} + 1 = \gamma.
\]

Finally, if \(x_n \geq 1 - x_{n-1}\) then
\[
\delta_n = \mu([0, 1] \setminus (X_n \cup X_1)) = \delta_{n-1} - (x_n + x_{n-1} - 1)
\]
\[
= \gamma + \eta_{n-1} + \eta_n - x_n - x_{n-1} - x_1 + \min\{x_{n-1}, x_1\} + 1 - \eta_{n-1}
\]
\[
= \gamma + \eta_{n-1} + (x_n + x_1 - 1) - x_n - x_{n-1} - x_1 + x_{n-1} + 1 - \eta_{n-1} = \gamma.
\]

**Case 2.2:** \(x_{n-1} > x_1\). In this case \(\delta_{n-1} = \mu(X_1 \setminus X_{n-1}) = \mu(X_1 \cup X_{n-1}) - x_{n-1}\). If \(x_n \leq 1 - x_{n-1}\) then
\[
\delta_n = \mu(X_n \cap X_1) = x_n - (1 - \mu(X_1 \cup X_{n-1})) = \delta_{n-1} - (1 - x_n - x_{n-1})
\]
\[
= \gamma + \eta_{n-1} + \eta_n - x_n - x_{n-1} - x_1 + \min\{x_{n-1}, x_1\} + 1 - (1 - x_n - x_{n-1})
\]
\[
= \gamma + 0 + 0 - x_n - x_{n-1} - x_1 + x_1 + 1 - (1 - x_n - x_{n-1}) = \gamma.
\]

If \(1 - x_{n-1} \leq x_n \leq 1 - x_1\) then
\[
\delta_n = \mu(X_n \cap X_1) = \mu(X_1 \setminus X_{n-1}) = \delta_{n-1}
\]
\[
= \gamma + \eta_{n-1} + \eta_n - x_n - x_{n-1} - x_1 + \min\{x_{n-1}, x_1\} + 1
\]
\[
= \gamma + (x_n + x_1 - 1) + 0 - x_n - x_{n-1} - x_1 + x_1 + 1 = \gamma.
\]

Finally, if \(x_n \geq 1 - x_1\) then
\[
\delta_n = \mu([0, 1] \setminus (X_n \cup X_1)) = \delta_{n-1} - (x_n + x_{n-1} - 1)
\]
\[
= \gamma + \eta_{n-1} + \eta_n - x_n - x_{n-1} - x_1 + \min\{x_{n-1}, x_1\} + 1 - \eta_{n-1}
\]
\[
= \gamma + (x_n + x_1 - 1) + \eta_n - x_n - x_{n-1} - x_1 + x_1 + 1 - \eta_{n-1} = \gamma.
\]

**Case 3:** \(n - 1 \in E^+, n \in E^-\). We may assume \(\mu(X_{n-1} \setminus X_1) < x_n < 1 - \mu(X_1 \setminus X_{n-1})\) since otherwise \(\delta_n = 0\).

**Case 3.1:** \(x_1 + x_{n-1} \leq 1\). In this case \(\delta_{n-1} = \mu(X_1 \cap X_{n-1})\).

If \(x_n \leq x_{n-1}\) then
\[
\delta_n = \delta_{n-1} - (x_{n-1} - x_n)
\]
\[
= \gamma - \mu_{n-1} + \eta_n + x_{n-1} - \max\{0, x_{n-1} + x_1 - 1\} - (x_{n-1} - x_n)
\]
\[
= \gamma - x_n + 0 + x_{n-1} - 0 - (x_{n-1} - x_n) = \gamma.
\]

If \(x_{n-1} \leq x_n \leq 1 - x_1\) then
\[
\delta_n = \delta_{n-1}
\]
\[
= \gamma - \mu_{n-1} + \eta_n + x_{n-1} - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
= \gamma - x_{n-1} + 0 + x_{n-1} - 0 = \gamma.
\]

Finally, if \(x_n \geq 1 - x_1\) then
\[
\delta_n = \delta_{n-1} - (x_1 + x_n - 1)
\]
\[
= \gamma - \mu_{n-1} + \eta_n + x_{n-1} - \max\{0, x_{n-1} + x_1 - 1\} - (x_1 + x_n - 1)
\]
\[
= \gamma - x_{n-1} + (x_1 + x_n - 1) + x_{n-1} - 0 - (x_1 + x_n - 1) = \gamma.
\]

**Case 3.2:** \(x_1 + x_{n-1} > 1\). In this case \(\delta_{n-1} = \mu([0, 1] \setminus (X_1 \cup X_{n-1}))\).

If \(x_n \leq 1 - x_1\) then
\[
\delta_n = \delta_{n-1} - (1 - x_1 - x_n)
\]
\[
= \gamma - \mu_{n-1} + \eta_n + x_{n-1} - \max\{0, x_{n-1} + x_1 - 1\} - (1 - x_1 - x_n)
\]
\[
= \gamma - x_n + 0 + x_{n-1} - (x_{n-1} + x_1 - 1) - (1 - x_1 - x_n) = \gamma.
\]
If $1 - x_1 \leq x_n \leq x_{n-1}$ then
\[
\delta_n = \delta_{n-1} - (x_1 - x_n)
\]
\[
\gamma + \eta_{n-1} + \mu_n + x_n - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
\gamma = \gamma - x_n + (x_n + 1) - x_{n-1} = \gamma.
\]
Finally, if $x_n \geq x_{n-1}$ then
\[
\delta_n = \delta_{n-1} - (x_n - x_{n-1})
\]
\[
\gamma = \gamma - \mu_{n-1} + \eta_n + x_{n-1} - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
\gamma = \gamma - x_n - x_{n-1} + x_{n-1} = \gamma.
\]

Case 4: $n - 1 \in E^-$, $n \in E^+$. We may assume $\mu(X_{n-1} \setminus X_1) < x_n < 1 - \mu(X_n \setminus X_1)$ since otherwise $\delta_n = 0$.

Case 4.1: $x_1 + x_{n-1} \leq 1$. In this case $\delta_{n-1} = \mu(X_1 \cap X_{n-1})$.

If $x_n \leq x_1$ then
\[
\delta_n = \delta_{n-1} - (x_1 - x_n)
\]
\[
\gamma + \eta_{n-1} - \mu_n + x_1 - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
\gamma = \gamma + 0 - x_n + x_1 - 0 = \gamma.
\]
If $x_1 \leq x_n \leq 1 - x_{n-1}$ then
\[
\delta_n = \delta_{n-1}
\]
\[
\gamma + \eta_{n-1} - \mu_n + x_1 - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
\gamma = \gamma + 0 - x_n + x_1 - 0 = \gamma.
\]
Finally, if $x_n \geq 1 - x_{n-1}$ then
\[
\delta_n = \delta_{n-1} - (x_n - x_{n-1})
\]
\[
\gamma + \eta_{n-1} - \mu_n + x_1 - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
\gamma = \gamma + 0 - x_n + x_1 - 0 = \gamma.
\]

Case 4.2: $x_1 + x_{n-1} > 1$. In this case $\delta_{n-1} = \mu([0, 1] \setminus (X_1 \cup X_{n-1}))$.

If $x_n \leq 1 - x_{n-1}$ then
\[
\delta_n = \delta_{n-1} - (1 - x_{n-1} - x_n)
\]
\[
\gamma + \eta_{n-1} - \mu_n + x_1 - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
\gamma = \gamma + 0 - x_n + x_1 - 0 - (x_n - x_{n-1}) = \gamma.
\]
If $1 - x_{n-1} \leq x_n \leq x_1$ then
\[
\delta_n = \delta_{n-1}
\]
\[
\gamma + \eta_{n-1} - \mu_n + x_1 - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
\gamma = \gamma + (x_{n-1} + x_n - 1) - x_{n-1} + x_1 - 0 = \gamma.
\]
Finally, if $x_n \geq x_1$ then
\[
\delta_n = \delta_{n-1} - (x_n - x_1)
\]
\[
\gamma + \eta_{n-1} - \mu_n + x_1 - \max\{0, x_{n-1} + x_1 - 1\}
\]
\[
\gamma = \gamma + (x_{n-1} + x_n - 1) - x_{n-1} + x_1 - 0 = \gamma.
