September 30, 2020

Abstract

The multilinear polytope $\text{MP}_G$ of a hypergraph $G = (V,E)$ is the convex hull of the set of binary points $z \in \{0,1\}^{V+E}$ satisfying the collection of multilinear equations $z_e = \prod_{v \in e} z_v$ for all $e \in E$. We introduce the running intersection inequalities, a new class of facet-defining inequalities for the multilinear polytope. Accordingly, we define a new polyhedral relaxation of $\text{MP}_G$ referred to as the running intersection relaxation and identify conditions under which this relaxation is tight. Namely, we show that for kite-free $\beta$-acyclic hypergraphs, a class that lies between $\gamma$-acyclic and $\beta$-acyclic hypergraphs, the running intersection relaxation coincides with $\text{MP}_G$ and it admits a polynomial size extended formulation.

Key words: multilinear polytope; running intersection property; hypergraph acyclicity; polyhedral relaxations; extended formulations.

1 Introduction

Multilinear sets and polytopes. Factorable reformulations of many types of Mixed Integer Nonlinear Programs (MINLP) contain a collection of multilinear equations of the form $z_e = \prod_{v \in e} z_v$, $e \in E$, where $E$ denotes a set of subsets of cardinality at least two of a ground set $V$. Important special cases include multilinear and polynomial optimization problems. Accordingly, we define the set

$$\left\{ z \in \{0,1\}^{V+E} : z_e = \prod_{v \in e} z_v, \forall e \in E \right\}. \quad (1)$$

In particular, the above set represents the feasible region of linearized binary polynomial optimization problems. There is a one-to-one correspondence between sets of form (1) and hypergraphs $G = (V,E)$ [12]. Henceforth, we refer to (1) as the multilinear set of $G$ and denote it by $\mathcal{S}_G$, and refer to its convex hull as the multilinear polytope of $G$ and denote it by $\text{MP}_G$.

If all multilinear equations defining $\mathcal{S}_G$ are bilinear, the multilinear polytope coincides with the Boolean quadric polytope defined by Padberg [25] in the context of unconstrained 0−1 quadratic optimization. In this case, our hypergraph representation simplifies to the graph representation defined by Padberg for the Boolean quadric polytope. Indeed, the Boolean quadric polytope is a well-known polytope in combinatorial optimization, and its facial structure has been thoroughly studied over the past three decades (see [16] for an exposition). In addition, these theoretical

findings have had a significant impact on the performance of mixed-integer quadratic optimization (MIQCP) solvers [2, 26, 24, 7]. In this paper, we consider multilinear sets containing higher degree multilinear equations and obtain new structural results for their convex hull with significant computational benefits for MINLPs.

There is an interesting connection between the complexity of the multilinear polytope and the acyclicity degree of its hypergraph. Padberg [25] shows that the Boolean quadric polytope admits a simple compact description, referred to as the standard linearization, if and only if the graph is acyclic. Subsequently, he introduces odd-cycle inequalities, a class of facet-defining inequalities arising from chordless cycles. The incorporation of these inequalities in general branch-and-cut based solvers has led to significant algorithmic improvements [3, 7, 26]. Motivated by this compelling line of research, it is natural to study the facial structure of the multilinear polytope of acyclic hypergraphs as the starting point. Interestingly, the notion of graph acyclicity has been extended to several different notions of hypergraph acyclicity: in increasing order of generality, one can name Berge-acyclicity, $\gamma$-acyclicity, $\beta$-acyclicity, and $\alpha$-acyclicity [18]. We should remark that polynomial time algorithms for determining acyclicity degree of hypergraphs are available [18]. In [13, 8], the authors show that the standard linearization coincides with the multilinear polytope if and only if the hypergraph is Berge-acyclic. In [13] the authors introduce “flower inequalities”, a generalization of 2-link inequalities [11], and show that the polytope obtained by adding all such inequalities to the standard linearization is the multilinear polytope if and only if the hypergraph is $\gamma$-acyclic. As the multilinear polytope of $\gamma$-acyclic hypergraphs may contain exponentially many facets, the authors present a strongly polynomial-time algorithm to solve the separation problem. This in turn implies that for a $\gamma$-acyclic hypergraph $G$, optimizing a linear function over $MP_G$ can be done in polynomial time.

Our contribution. The next type of acyclic hypergraphs is the class of $\beta$-acyclic hypergraphs. We believe that the multilinear polytope in this case has a significantly more complex structure than the multilinear polytope of $\gamma$-acyclic hypergraphs. In particular, it can be checked that the multilinear polytope of $\beta$-acyclic hypergraphs can have dense facet-defining inequalities. By dense facets, we mean facets whose support hypergraph contains almost all edges of the original hypergraph, a property which is not desirable from a computational perspective. This is in major contrast with the multilinear polytope of $\gamma$-acyclic hypergraphs whose defining inequalities are fairly sparse.

With the objective of constructing stronger polyhedral relaxations for multilinear sets of general hypergraphs which can also be effectively incorporated in branch-and-cut based MINLP solvers, in this paper we introduce a new class of sparse facet-defining inequalities for the multilinear polytope. The proposed inequalities, referred to as “running intersection inequalities,” serve as a significant generalization of flower inequalities [13].

As we detail in Section 2, the support hypergraph of a running intersection inequality consists of a center edge $e_0$ together with a number of neighbor edges $e_k$, $k \in K$, that are adjacent to $e_0$. The support hypergraph of flower inequalities has the same structure, with the additional assumption that $e_0 \cap e_k \cap e_{k'} = \emptyset$ for all $k, k' \in K$. The support hypergraph of running intersection inequalities however, may contain nonempty intersections among multiple neighbors with the center edge, which amounts to the presence of $\gamma$-cycles. This, in turn, makes the proposed inequalities applicable to a much broader class of hypergraphs. Our generalization relies on the key notion of “running intersection property”, a set theoretic concept first introduced in the database community to study acyclic databases [4]. As we demonstrate in Section 2.5, this generalization has significant computational implications. That is, by employing running intersection cuts instead of flower cuts
we are able to obtain much stronger relaxations for a class of fourth order binary polynomial optimization problems that arise from an application in computer vision. Furthermore, in [15], the authors investigate the impact of the proposed inequalities on the convergence rate of the global solver BARON [20]. Results on various types of polynomial optimization problems indicate that running intersection cuts significantly improve the performance of BARON and lead to an average 50% CPU time reduction.

To better understand the theoretical limits of the proposed inequalities, we define the running intersection relaxation, a new polyhedral relaxation for the multilinear set obtained by adding all running intersection inequalities to its standard linearization. We show that for kite-free $\beta$-acyclic hypergraphs, a class that lies between $\gamma$-acyclic hypergraphs and $\beta$-acyclic hypergraphs, the running intersection relaxation coincides with the multilinear polytope (see Theorem 3). In addition, for a kite-free $\beta$-acyclic hypergraph $G = (V, E)$, we present a compact extended formulation of the multilinear polytope (see Theorem 2). More precisely, if all edges of $G$ have cardinality at most $r$, the proposed extended formulation has at most $|V| + 2|E|$ variables and $2(|V| + (r + 2)|E|)$ inequalities, while the multilinear polytope in the original space may contain exponentially many facet-defining inequalities. This in turn implies that optimizing a linear function over $\text{MP}_G$ can be done in polynomial time. The proposed extended formulation is obtained by showing that, after the addition of at most $|E|$ edges to the original hypergraph $G$, the corresponding multilinear polytope can be expressed as the intersection of a collection of multilinear polytopes $\text{MP}_G^j$, $j \in J$, where each polytope $\text{MP}_G^j$ has a compact description. To this end, we present a new sufficient condition for decomposability of multilinear sets, a result which is of independent interest (see Theorem 1).

There has been an interesting line of research [27, 22, 21, 6] which relates the complexity of the convex hull of a binary set defined by a system of polynomial inequalities to the treewidth of a corresponding intersection graph. Namely, it has been shown that if the intersection graph has constant treewidth, the convex hull has an extended formulation of polynomial size. We derive an alternative statement of this result in terms of the acyclicity degree of the underlying hypergraph (see Theorem 5). This new interpretation enables us to compare and contrast this existing result against ours. In particular we show that neither of the two results is implied by the other one.

Organization. In Section 2 we introduce running intersection inequalities, we establish some of their basic properties, and we identify conditions under which they induce facets of the multilinear polytope. In Section 3 we show that the running intersection relaxation coincides with the multilinear polytope of kite-free $\beta$-acyclic hypergraphs. We compare our characterization against the treewidth based approach in Section 4. Finally, proofs of the technical results omitted in the previous sections are given in Section 5.

2 The running intersection relaxation

We start by formally introducing some hypergraph terminology. A hypergraph $G$ is a pair $(V, E)$, where $V$ is a finite set of nodes and $E$ is a multiset of subsets of $V$, called the edges of $G$. Unless stated otherwise, throughout this paper we consider hypergraphs without loops or parallel edges, in which case $E$ is a set of subsets of $V$ of cardinality at least two. We refer to the node set of $G$ as $V(G)$ and to the edge set of $G$ as $E(G)$. We say that two edges are adjacent if they have nonempty intersection. We define the support hypergraph of a valid inequality $az \leq \alpha$ for $\text{MP}_G$, as the hypergraph $G(a)$, where $V(G(a)) = \{v \in V : a_v \neq 0\} \cup (\cup_{e \in E : a_e \neq 0} e)$, and $E(G(a)) = \{e \in E : a_e \neq 0\}$.

In [13], we introduced flower inequalities, a class of facet-defining inequalities for the multilinear
polytope whose support hypergraphs are $\gamma$-acyclic. In this section, we present a significant generalization of these inequalities that does not require $\gamma$-acyclicity of the support hypergraph. To obtain the new cutting planes, we make use of the notion of running intersection property, which was introduced in the database community to study acyclic databases [4] and has been used by the machine learning community to infer conditional independence in graphical models [23].

2.1 The running intersection property

A multiset $F$ of subsets of a finite set $V$ has the running intersection property if there exists an ordering $p_1, p_2, \ldots, p_m$ of the sets in $F$ such that

$$\text{for each } k = 2, \ldots, m, \text{ there exists } j < k \text{ such that } p_k \cap \left( \bigcup_{i<k} p_i \right) \subseteq p_j.$$  \hspace{1cm} (2)

Throughout the paper, we refer to an ordering $p_1, p_2, \ldots, p_m$ satisfying (2) as a running intersection ordering of $F$. See Figure 1 for an illustration. Each running intersection ordering $p_1, p_2, \ldots, p_m$ of $F$ induces a collection of sets

$$N(p_1) := \emptyset, \quad N(p_k) := p_k \cap \left( \bigcup_{i<k} p_i \right) \text{ for } k = 2, \ldots, m.$$  \hspace{1cm} (3)

Figure 1: A multiset with the running intersection property. A running intersection ordering is given by $p_1, p_2, p_3, p_4, p_5, p_6, p_7, p_8$.

It can be shown that if a multiset $F$ with $|F| \geq 2$ has the running intersection property, then there exist several running intersection orderings of $F$. We refer to an element $f \in F$ as a leaf of $F$ if there exists a running intersection ordering of $F$ in which $f$ is the last element. The following lemma states some basic properties of multisets with the running intersection property and has been stated in various forms in the literature (see for example [4]).

**Lemma 1.** Let $F$ be a multiset with the running intersection property. If $|F| \geq 2$, then:

(i) $F$ has at least two leaves;

(ii) For any $f \in F$, there exists a running intersection ordering of $F$ in which $f$ is the first element;

(iii) For any $f \in F$ such that $f \subseteq f'$ for some $f' \in F$, the multiset $F \setminus \{f\}$ has the running intersection property.

As we detail in the following, to obtain running intersection inequalities we make use of the number of connected components of a related hypergraph. We now formalize the concept of hypergraph connectivity. We first present the notion of a chain in a hypergraph as defined in [5]. A chain in $G$ of length $t$ for some $t \geq 1$, is a sequence $P = v_1, e_1, v_2, e_2, \ldots, e_t, v_{t+1}$ such that $v_1, v_2, \ldots, v_t$
are distinct nodes of \( G, e_1, e_2, \ldots, e_t \) are distinct edges of \( G \), and \( v_i, v_{i+1} \in e_i \) for \( i = 1, \ldots, t \). A hypergraph \( G \) is connected if for any two distinct nodes \( v_i, v_j \) of \( G \), there is a chain between \( v_i \) and \( v_j \) in \( G \). Consider a hypergraph \( G = (V, E) \) and let \( V' \) be a subset of \( V \). A hypergraph \((V', E')\) is a partial hypergraph of \( G \) if \( E' \subseteq E \). The section hypergraph of \( G \) induced by \( V' \) is the partial hypergraph \((V', E')\), where \( E' = \{ e \in E : e \subseteq V' \} \). The connected components of \( G \) are the maximal connected section hypergraphs of \( G \). We refer to a node of \( G \) as an isolated node if it is not contained in any edge of \( G \). Note that an isolated node corresponds to a connected component.

The next lemma provides an alternative characterization for the number of connected components of a hypergraph whose edge set has the running intersection property.

**Lemma 2.** Let \( G = (V, E) \) be a hypergraph. Assume that there exists a running intersection ordering \( e_1, \ldots, e_m \) of \( E \) and denote by \( N(e_1), \ldots, N(e_m) \) the corresponding sets defined in (3). Then the number of connected components of \( G \) is

\[
n_0 + |\{ e \in E : N(e) = \emptyset \}|,
\]

where \( n_0 \) is the number of isolated nodes of \( G \).

**Proof.** To prove the statement, it suffices to show that the number \( \omega \) of connected components of a hypergraph \( G \) with no isolated nodes is \(|\{ e \in E : N(e) = \emptyset \}|\). The proof is by induction on \( m = |E| \), the base case being trivial. Let \( G' = (V', E') \) be the hypergraph with node set \( V' := \bigcup_{k=1}^{m-1} e_k \) and edge set \( E' := \{ e_1, \ldots, e_{m-1} \} \). Note that \( e_1, \ldots, e_{m-1} \) is a running intersection ordering of \( E' \) and that the corresponding sets \( N'(e_k) = N(e_k) \) for all \( k = 1, \ldots, m - 1 \). Thus by induction the number \( \omega' \) of connected components of \( G' \) is \(|\{ e \in E' : N(e) = \emptyset \}|\). First consider the case \( e_m \cap E' = \emptyset \). In this case \( N(e_m) = \emptyset \) and \( G \) has one more connected component than \( G' \); that is,

\[
\omega = \omega' + 1 = |\{ e \in E' : N(e) = \emptyset \}| + 1 = |\{ e \in E : N(e) = \emptyset \}|.
\]

Next, consider the case \( e_m \cap E' \neq \emptyset \). It then follows that \( N(e_m) \neq \emptyset \) and \( G \) has the same number of connected component as \( G' \). Thus

\[
\omega = \omega' = |\{ e \in E' : N(e) = \emptyset \}| = |\{ e \in E : N(e) = \emptyset \}|.
\]

We are now in a position to define running intersection inequalities.

### 2.2 Running intersection inequalities

Consider a hypergraph \( G = (V, E) \). Let \( e_0 \in E \) and let \( e_k, k \in K \), be a collection of edges adjacent to \( e_0 \) in \( G \) such that the multiset

\[
\tilde{E} := \{ e_0 \cap e_k : k \in K \}
\]

has the running intersection property. Consider a running intersection ordering of \( \tilde{E} \) with the corresponding sets \( N(e_0 \cap e_k) \), for \( k \in K \), as defined in (3). For each \( k \in K \) with \( N(e_0 \cap e_k) \neq \emptyset \), let \( u_k \) be a node in \( N(e_0 \cap e_k) \). We define a running intersection inequality as

\[
- \sum_{k \in K : N(e_0 \cap e_k) \neq \emptyset} z_{u_k} + \sum_{v \in e_0 \setminus \bigcup_{k \in K} e_k} z_v + \sum_{k \in K} z_{e_k} - z_{e_0} \leq \omega - 1,
\]

where \( \omega \) is the number of connected components of the hypergraph \( \tilde{G} = (e_0, \tilde{E}) \). We refer to \( e_0 \) as the center and to \( e_k, k \in K \), as the neighbors. Note that unlike \( G \), the hypergraph \( \tilde{G} \) may
have loops and parallel edges. By Lemma\(^2\) the right-hand side of (5) is equal to the sum of the coefficients of the left-hand side. In the special case where \(N(e_0 \cap e_k) = \emptyset\) for all \(k \in K\), i.e., \(e_0 \cap e_k \cap e_{k'} = \emptyset\) for all \(k, k' \in K\), running intersection inequalities simplify to flower inequalities introduced in [13].

We now establish the validity of running intersection inequalities for \(\text{MP}_G\).

**Proposition 1.** Running intersection inequalities are valid for the multilinear polytope.

**Proof.** Consider a running intersection inequality (5). Let \(G = (e_0, E)\) be the corresponding hypergraph where \(E\) is defined by (4), and let \(O\) denote a running intersection ordering of \(E\) with the sets \(N(e_0 \cap e_k), k \in K\), as defined in (3). Denote by \(O_i, i = 1, \ldots, \omega\), the connected components of \(G\). For each \(G_i\), define \(K_i = \{k \in K : e_k \cap e_0 \in E(G_i)\}\). Clearly, the sets \(K_i\), for \(i = 1, \ldots, \omega\), form a partition of \(K\). We argue that for each \(G_i\) with \(K_i \neq \emptyset\), the following inequality is valid for \(\text{MP}_G\).

\[
- \sum_{k \in K_i : N(e_0 \cap e_k) \neq \emptyset} z_{uk} + \sum_{k \in K_i} z_{ek} \leq 1. 
\]

(6)

If \(|K_i| = 1\), say \(K_i = \{1\}\), then \(N(e_0 \cap e_1) = \emptyset\); thus the validity of (6) is trivial. Henceforth, assume that \(|K_i| \geq 2\). We claim that the maximum value of the left-hand side of inequality (6) is one, and this value is attained if and only if \(z_{e_{k}} = 1\) for all \(k \in K_i\). Let \(O_i\) be the subsequence of \(O\) corresponding to the edges \(e_0 \cap e_k\), with \(k \in K_i\). It can be shown that \(O_i\) is a running intersection ordering of \(E(G_i)\). Without loss of generality, let \(O_i = e_0 \cap e_1, e_0 \cap e_2, \ldots, e_0 \cap e_t\), where \(t := |E(G_i)|\). Since \(G_i\) is a connected hypergraph by Lemma\(^2\) we have \(N(e_0 \cap e_k) \neq \emptyset\) for all \(k = 2, \ldots, t\). This implies that for each \(k = 2, \ldots, t\), the node \(u_k\) exists and if \(z_{e_{k}} = 1\), we have \(z_{u_{k}} = 1\). Consequently the value of the left-hand side of inequality (6) is at most one and if it is equal to one, we must have \(z_{e_{1}} = 1\). Now suppose that \(z_{e_{1}} = 1\). Since \(u_2 \in e_1\), it follows that \(z_{u_{2}} = 1\). Hence, if the maximum value of the left-hand side of (6) is attained, we must have \(z_{e_{2}} = 1\). If \(t = 2\), the proof is complete. Otherwise, since \(u_3\) is in \(e_1\) or in \(e_2\) and \(z_{e_{1}} = z_{e_{2}} = 1\), we have \(z_{u_{3}} = 1\) which in turn implies \(z_{e_{3}} = 1\). Hence, by a recursive application of this argument for each element of \(O_i\), we conclude that inequality (6) is binding if and only if \(z_{e_{k}} = 1\) for all \(k \in K_i\).

By summing up inequalities (6) for all \(G_i\) with \(E(G_i) \neq \emptyset\) together with inequalities \(z_{v_i} \leq 1\) for all \(G_i\) with \(V(G_i) = \{v_i\}\) and \(E(G_i) = \emptyset\), we conclude that the value of the three summations on the left hand side of (5) does not exceed \(\omega\). In addition, this maximum value is attained only if \(z_{e_{k}} = 1\) for all \(k \in K\) and \(z_v = 1\) for all \(v \in e_0 \setminus (\cup_{k \in K} e_{k})\) which in turn implies \(z_{e_0} = 1\). Hence, inequality (4) is valid. \(\Box\)

**Example 1.** Consider the hypergraph \(G = (V, E)\) with \(V = \{v_1, \ldots, v_7\}\) and \(E = \{e_0, e_1, e_2, e_3, e_4\}\), where we define \(e_0 := V, e_1 := \{v_1, v_2, v_3, v_7\}, e_2 := \{v_2, v_3, v_6\}, e_3 := \{v_1, v_3, v_5\}, e_4 := \{v_1, v_2, v_4\}\) (see Figure 2). Consider the set \(E = \{e \cap e_0 : e \in E \setminus \{e_0\}\}\). It is then simple to see that the sequence \(O = e_1, e_2, e_3, e_4\) is a running intersection ordering of \(E\). By (3) we have \(N(e_0 \cap e_1) = \{v_1, v_2\}\), \(N(e_0 \cap e_3) = \{v_1, v_3\}\), \(N(e_0 \cap e_2) = \{v_2, v_3\}\). Hence, the system of running intersection inequalities centered at \(e_0\) with neighbors \(E \setminus \{e_0\}\) is given by

\[
-2z_{v_1} - z_{v_2} - z_{e_0} + z_{e_1} + z_{e_2} + z_{e_3} + z_{e_4} \leq 0 \quad \text{for all distinct pairs } (i, j) \in \{1, 2, 3\}. \]

(7)

It can be checked that all of the above inequalities define facets of \(\text{MP}_G\). Note that one can write many more running intersection inequalities for \(\text{MP}_G\). Due to space limitations, we only listed those centered at \(e_0\) with neighbors \(E \setminus \{e_0\}\). \(\diamond\)
Consider the set of all running intersection inequalities centered at $e_0$ with neighbors $e_k$, $k \in K$. To construct these inequalities, we make use of a running intersection ordering of the multiset $\bar{E}$ defined by (1), and by Lemma (1) such an ordering is not unique. However, the following proposition implies that the system of all running intersection inequalities centered at $e_0$ with neighbors $e_k$, $k \in K$, is independent of the running intersection ordering.

**Proposition 2.** Let $F$ be a multiset with the running intersection property. Then any running intersection ordering of $F$ leads to the same multiset $\{N(e) : e \in F\}$ as defined in (3).

**Proof.** We prove the statement by induction on $|F|$. Given a multiset $F'$ of subsets of a finite set and $e,f \in F'$, we say that $e$ is a parent of $f$ in $F'$ if $f \cap \bigcup_{g \in F' \setminus f} g \subseteq e$.

In the base case we have $|F| = 1$; the running intersection ordering is unique and thus the statement trivially follows. We also consider the base case $|F| = 2$. Let $f,g \in F$. If $f \cap g = \emptyset$, then independent of the running intersection ordering, we obtain $N(f) = N(g) = \emptyset$. Thus, we assume that $f \cap g$ is nonempty. Let $O$ be a running intersection ordering of $F$. If $O = g,f$, we obtain $N(f) = f \cap g$ and $N(g) = \emptyset$. Vice versa, if $O = f,g$, we obtain $N'(g) = g \cap f$ and $N'(f) = \emptyset$. Hence the two multisets coincide. Note that in the latter base case, even though the two multisets coincide, the function that associates to each $e \in F$ the set $N(e)$ is not independent of the running intersection ordering.

We now prove the inductive step. Let $O$ and $O'$ be two running intersection orderings of $F$. Let $\{N(e) : e \in F\}$ be the multiset corresponding to $O$ and let $\{N'(e) : e \in F\}$ be the multiset corresponding to $O'$. If the last set in $O$ and $O'$ is the same set, say $f$, then we have $N(f) = N'(f)$. By dropping the last set from $O$ and $O'$ we obtain two running intersection orderings $\bar{O}$ and $\bar{O}'$ of $F \setminus \{f\}$, respectively. By induction the two multisets $\{N(e) : e \in F \setminus \{f\}\}$ and $\{N'(e) : e \in F \setminus \{f\}\}$ coincide, hence also the multisets $\{N(e) : e \in F\}$ and $\{N'(e) : e \in F\}$ coincide. Thus we now assume that the last set in $O$, say $f$, is different from the last set in $O'$, say $g$.

Since $f$ and $g$ are leaves of $F$, they both have a parent in $F$. Let $p(f)$ be a parent of $f$ in $F$, and let $p(g)$ be a parent of $g$ in $F$. Note that there might be several sets of $F$ that are parents of $f$. If $g$ is a parent of $f$, then we set $p(f) := g$. Symmetrically, if $f$ is a parent of $g$, then we set $p(g) := f$.

We first consider the case where $p(f) = g$ and $p(g) = f$. Since $p(g) = f$, for every set $e \in F \setminus \{f\}$ we have $g \cap e = f \cap g \cap e$. Let $\bar{F}$ be obtained from $F \setminus \{f\}$ by replacing the set $g$ with a new set $f \cap g$ and let $\bar{O}$ be obtained from $O$ by dropping the last set $f$ and by replacing $g$ with $f \cap g$. Since by dropping the last set from $O$ we obtain a running intersection ordering of $F \setminus \{f\}$, it can be checked that $\bar{O}$ is a running intersection ordering of $\bar{F}$ and that the two running intersection orderings lead to the same multiset $\{N(e) : e \in F \setminus \{f\}\}$. Symmetrically, since $p(f) = g$, we define...
the set $\tilde{F}'$ obtained from $F \setminus \{g\}$ by replacing the set $f$ with a new set $f \cap g$. We also obtain $\tilde{O}'$ from $O'$ by dropping the last set $g$ and by replacing $f$ with $f \cap g$. As above, $\tilde{O}'$ is a running intersection ordering of $\tilde{F}'$. Moreover $\tilde{O}'$ and the running intersection ordering of $F \setminus \{g\}$ obtained by dropping the last set from $O'$ lead to the same multiset $\{N'(e) : e \in F \setminus \{g\}\}$. Note that $F = \tilde{F}'$, thus by induction the two multiset $\{N(e) : e \in F \setminus \{f\}\}$ and $\{N'(e) : e \in F \setminus \{g\}\}$ coincide. Since $N(f) = f \cap g = N'(g)$, also the multisets $\{N(e) : e \in F\}$ and $\{N'(e) : e \in F\}$ coincide. This concludes the proof in the case $p(f) = g$ and $p(g) = f$.

We now assume that the assumption $p(g) = f$ and $p(f) = g$ does not hold. To study the multiset $\{N(e) : e \in F\}$ corresponding to $O$, we define the multiset $F_1$ obtained from $F$ by deleting the set $f$.

Claim 1. If $p(g) \neq f$, then $p(g)$ is a parent of $g$ in $F_1$. If $p(g) = f$, then $p(f)$ is a parent of $g$ in $F_1$.

Proof of claim. If $p(g) \neq f$, then $p(g)$ is a parent of $g$ in $F_1$ since

$$g \cap (\cup_{e \in F \setminus \{f,g\}} e) \subseteq g \cap (\cup_{e \in F \setminus \{g\}} e) \subseteq p(g).$$

Assume now that $p(g) = f$. We have $g \cap (\cup_{e \in F \setminus \{f,g\}} e) \subseteq g \cap (\cup_{e \in F \setminus \{g\}} e) \subseteq f$, and $\cup_{e \in F \setminus \{f,g\}} e \subseteq \cup_{e \in F \setminus \{f\}} e$. Thus,

$$g \cap (\cup_{e \in F \setminus \{f,g\}} e) \subseteq f \cap (\cup_{e \in F \setminus \{f\}} e) \subseteq p(f).$$

Since $p(f) \neq g$, it follows that $p(f)$ is a parent of $g$ in $F_1$.

By Claim 1, $g$ has a parent in $F_1$. This implies that there exists a running intersection ordering of $F \setminus \{f\}$ with $g$ as the last set. In fact, such a running intersection ordering can be obtained by appending $g$ to a running intersection ordering of $F \setminus \{f,g\}$. Since by induction all running intersection orderings of $F \setminus \{f\}$ lead to the same multiset, we assume without loss of generality that the second to last set in $O$ is $g$. We now explicitly write the obtained sets $N(f)$ and $N(g)$. To do so, we consider three cases: (A) $p(f) \neq g$ and $p(g) \neq f$, (B) $p(f) = g$ and $p(g) \neq f$, (C) $p(f) \neq g$ and $p(g) = f$.

Case (A). We have $N(f) = f \cap p(f)$ and by Claim 1, $N(g) = g \cap p(g)$.

Case (B). We have $N(f) = f \cap g$ and by Claim 1, $N(g) = g \cap p(g)$.

Case (C). We have $N(f) = f \cap p(f)$ and by Claim 1, $N(g) = g \cap p(f)$.

We now study the multiset $\{N'(e) : e \in F\}$ corresponding to $O'$. Let $F'_1$ be obtained from $F$ by deleting the set $g$. By Claim 1, with $f$ and $g$ permuted, and with $F'_1$ instead of $F_1$, we obtain

Claim 2. If $p(f) \neq g$, then $p(f)$ is a parent of $f$ in $F'_1$. If $p(f) = g$ then $p(g)$ is a parent of $f$ in $F'_1$.

By Claim 2, $f$ has a parent in $F'_1$. This implies that there exists a running intersection ordering of $F \setminus \{g\}$ with $f$ as the last set. Since by induction all running intersection orderings of $F \setminus \{g\}$ lead to the same multiset, we assume without loss of generality that the second to last set in $O'$ is $f$. In order to explicitly write the obtained sets $N'(g)$ and $N'(f)$, we consider the three cases (A), (B), (C) introduced above.

Case (A). We have $N'(g) = g \cap p(g)$ and by Claim 2, $N'(f) = f \cap p(f)$.

Case (B). We have $N'(g) = g \cap p(g)$ and by Claim 2, $N'(f) = f \cap p(g)$.

Case (C). We have $N'(g) = g \cap f$ and by Claim 2, $N'(f) = f \cap p(f)$.

We now show that the multiset $\{N(f), N'(g)\}$ equals the multiset $\{N'(g), N'(f)\}$. This concludes the proof of the proposition since the two orders obtained from $O$ and $O'$ by dropping the last
two sets are running intersection orderings of the same set \( F \setminus \{f, g\} \) and by induction the two corresponding multisets coincide.

Again, we consider the three cases (A), (B), (C). As the case (C) is symmetric to case (B), we will not consider it any further.

Case (A). We have \( N(f) = N'(f) \), and \( N(g) = N'(g) \). Thus we are done.

Case (B). We have \( N(g) = N'(g) \). Thus we need to show \( N(f) = f \cap g = f \cap p(g) = N'(f) \). Since \( p(g) \) is a parent of \( g \) in \( F \), we have \( f \cap g \subseteq p(g) \), thus \( f \cap g \subseteq f \cap p(g) \). Vice versa, since \( g \) is a parent of \( f \) in \( F \), we have \( f \cap p(g) \subseteq g \), thus \( f \cap p(g) \subseteq f \cap g \).

By applying Proposition 2 to the multiset \( \tilde{E} \) defined by (4), we obtain the following result.

**Corollary 1.** Any running intersection ordering of \( \tilde{E} \) leads to the same system of running intersection inequalities centered at \( e_0 \) with neighbors \( e_k, k \in K \).

We now introduce a new polyhedral relaxation of multilinear sets. To this end, we first recall a widely-used polyhedral relaxation of \( S_G \), which is obtained by replacing each multilinear equation \( z_e = \prod_{v \in e} z_v \), by its convex hull over the unit hypercube:

\[
\text{MP}^P_G := \left\{ z : \ z_v \leq 1, \ \forall v \in V, \quad z_e \geq 0, \ z_e \geq \sum_{v \in e} z_v - |e| + 1, \ \forall e \in E, \right. \\
\left. z_e \leq \ z_v, \ \forall e \in E, \ \forall v \in e \right\}.
\] (8)

The above relaxation has been used extensively in the literature and is often referred to as the standard linearization of the multilinear set (see, e.g., [10]).

We define the running intersection relaxation of \( S_G \), denoted by \( \text{MP}^\text{RI}_G \), as the polytope obtained by adding to \( \text{MP}^P_G \) all possible running intersection inequalities for \( S_G \). Note that running intersection inequalities with no neighbors are already present in (8).

### 2.3 Redundant inequalities

For a general hypergraph \( G \), many of the running intersection inequalities defined by (5) are redundant for \( \text{MP}^\text{RI}_G \). The following proposition provides sufficient conditions to identify such redundant inequalities.

**Proposition 3.** Every running intersection inequality centered at \( e_0 \) with neighbors \( e_k, k \in K \), that defines a facet of \( \text{MP}^\text{RI}_G \) satisfies the following three conditions:

(i) \( e_0 \cap e_k \not\subseteq e_0 \cap e_{k'} \) for any \( k, k' \in K \);

(ii) \( |e_0 \cap e_k| \geq 2 \) for all \( k \in K \);

(iii) For any distinct \( k, k' \in K \) with \( u_k, u_{k'} \in N(e_0 \cap e_k) \cap N(e_0 \cap e_{k'}) \), we have \( u_k = u_{k'} \).

**Proof.** To prove the statement, we consider a running intersection inequality not satisfying each condition. Then we show that such an inequality can be obtained by summing up a number of other inequalities valid for \( \text{MP}^\text{RI}_G \). Since \( \text{MP}_G \) is full dimensional [12], this implies that the inequality under consideration is not facet-defining.

Consider a running intersection inequality centered at \( e_0 \) with neighbors \( e_k, k \in K \). Assume that this inequality does not satisfy condition (i), i.e. there exist \( i, j \in K \) such that \( e_0 \cap e_i \subseteq e_0 \cap e_j \).
Consider the multiset $\tilde{E}$ defined by (4). We show that there exists a running intersection ordering $O$ of $\tilde{E}$ in which $e_0 \cap e_j$ appears before $e_0 \cap e_i$. Define $\tilde{E}' = \{e_0 \cap e_k : k \in K \setminus \{i\}\}$. Observe that by part (iii) of Lemma 1 the set $\tilde{E}'$ has the running intersection property. Consider a running intersection ordering $O'$ of $\tilde{E}'$ and construct a sequence $O$ obtained by inserting $e_0 \cap e_i$ right after $e_0 \cap e_j$ in $O'$. It is now simple to check that $O$ is a running intersection ordering of $\tilde{E}$. A running intersection inequality centered at $e_0$ with neighbors $e_k$, $k \in K \setminus \{i\}$, is given by

$$-\sum_{k \in K \setminus \{i\} : N(e_0 \cap e_k) \neq \emptyset} z_{u_k} + \sum_{v \in e_0 \setminus \bigcup_{k \in K \setminus \{i\}} e_k} z_v + \sum_{k \in K \setminus \{i\}} z_{e_k} - z_{e_0} \leq \omega - 1,$$

where $\omega$ denotes the number of connected components of $\tilde{G}' = (e_0, \tilde{E}')$ and the sets $N(e_0 \cap e_k)$, $k \in K \setminus \{i\}$ are obtained according to the running intersection ordering $O'$. Now consider the edge $e_i$ and denote by $u$ a node in $e_0 \cap e_i$. Then the following inequality is present in $MP_G^{LP}$:

$$-z_u + z_{e_i} \leq 0.$$

It is simple to see that $e_0 \setminus \bigcup_{k \in K} e_k = e_0 \setminus \bigcup_{k \in K \setminus \{i\}} e_k$. Moreover, the number of connected components of the two hypergraphs $\tilde{G} = (e_0, \tilde{E})$ and $\tilde{G}'$ are identical. In addition, by construction, the sets $N(e_0 \cap e_k)$, $k \in K \setminus \{i\}$, associated with $O'$ coincide with those associated with $O$. Finally, the set $N(e_0 \cap e_i)$ obtained using $O$ is given by $N(e_0 \cap e_i) = e_0 \cap e_i$, since by assumption $e_0 \cap e_i \subseteq e_0 \cap e_j$ and $e_0 \cap e_j$ appears before $e_0 \cap e_i$. It then follows that the running intersection inequality under consideration can be obtained by adding inequalities (9) and (10).

Consider a running intersection inequality centered at $e_0$ with neighbors $e_k$, $k \in K$. Assume that this inequality does not satisfy condition (ii), i.e. there exist $i \in K$ and $u \in V(G)$ such that $e_0 \cap e_i = \{u\}$. We can assume that the inequality satisfies condition (i); thus we have $u \not\in e_k \cap e_0$ for every $k \in K \setminus \{i\}$. Consider a running intersection ordering $O$ of $\tilde{E}$ defined by (4) and let the set $N(e_0 \cap e_k)$, $k \in K$, be defined by (3). It then follows that $N(e_0 \cap e_i) = \emptyset$ and that the sequence $O'$ obtained by removing $e_0 \cap e_i$ from $O$ is a running intersection ordering of the set $\tilde{E}' = \{e_0 \cap e_k : k \in K \setminus \{i\}\}$. In addition, the sets $N(e_0 \cap e_k)$, $k \in K \setminus \{i\}$, associated with $O'$ are identical to those associated with $O$. Hence, a running intersection inequality centered at $e_0$ with neighbors $e_k$, $k \in K \setminus \{i\}$ is given by

$$-\sum_{k \in K : N(e_0 \cap e_k) \neq \emptyset} z_{u_k} + \sum_{v \in e_0 \setminus \bigcup_{k \in K \setminus \{i\}} e_k} z_v + \sum_{k \in K \setminus \{i\}} z_{e_k} - z_{e_0} \leq \omega - 1,$$

where $\omega$ denotes the number of connected components of the hypergraph $\tilde{G}' = (e_0, \tilde{E}')$. Now consider the edge $e_i$; clearly, the following inequality is present in $MP_G^{LP}$:

$$-z_u + z_{e_i} \leq 0.$$

It is simple to see that $e_0 \setminus \bigcup_{k \in K \setminus \{i\}} e_k = \{u\} \cup (e_0 \setminus \bigcup_{k \in K} e_k)$. In addition, the number of connected components of $\tilde{G} = (e_0, \tilde{E})$ and $\tilde{G}'$ are identical. It then follows that the running intersection inequality under consideration can be obtained by summing up inequalities (11) and (12).

Finally, consider a running intersection inequality centered at $e_0$ with neighbors $e_k$, $k \in K$ that does not satisfy condition (iii); i.e., there exist $i, j \in K$ with $u_i, u_j \in N(e_0 \cap e_i) \cap N(e_0 \cap e_j)$ such that $u_i \neq u_j$. We now construct two other running intersection inequalities entered at $e_0$ with neighbors $e_k$, $k \in K$, for which we select the same node from each $N(e_0 \cap e_k)$, for all $k \in K \setminus \{i, j\}$ as the original inequality, but for first one we let $u'_i = u'_j = u_i$, while for the second one we let $u''_i = u''_j = u_j$. It is then simple to check that the running intersection inequality under consideration can be obtained by adding these two inequalities both of which are present in $MP_G^{RI}$. \(\square\)
2.4 Facet-defining inequalities

We conclude this section by showing that, under certain assumptions, running intersection inequalities are facet-defining for their support hypergraphs. This result together with the lifting theorems presented in [12] enables us to obtain sufficient conditions under which these inequalities define facets of the multilinear polytope of general hypergraphs.

**Proposition 4.** Consider a running intersection inequality centered at $e_0$ with neighbors $e_k$, $k \in K$, and let $G$ denote its support hypergraph. Assume that the inequality satisfies the following conditions:

1. $|e_0 \cap e_k| \geq 2$ for all $k \in K$;
2. For every $K' \subseteq K$ such that $e_0 \cap (\cap_{k \in K'} e_k) \neq \emptyset$ we have $e_0 \cap (e_i \setminus \cup_{k \in K' \setminus \{i\}} e_k) \neq \emptyset$ for all $i \in K'$;
3. Each nonempty $N(e_0 \cap e_k)$, $k \in K$, intersects the set $U := \{u_k : k \in K, N(e_0 \cap e_k) \neq \emptyset\}$ in only one node.

Then this running intersection inequality defines a facet of $MP_G$.

**Proof.** Consider a running intersection inequality defined by (5). We start by identifying a set of points in $S_G$ that satisfy this inequality tightly. Subsequently, we show that any nontrivial valid inequality $az \leq \alpha$ for $S_G$ that is satisfied tightly at all such points coincides with (5) up to a positive scaling. Since $MP_G$ is full dimensional [12], this in turn implies that inequality (5) defines a facet of $MP_G$.

Let $\tilde{G} = (e_0, \tilde{E})$, where $\tilde{E}$ is given by (4). As in the proof of Proposition 1, we denote by $\tilde{G}_1, \ldots, \tilde{G}_\omega$ the connected components of $\tilde{G}$. Consider a partition of $K$ given by $K = \bigcup_{i=1}^\omega K_i$, where $K_i$ contains the indices of the edges of $\tilde{G}_i$. Let $\Omega$ contain those indices $i \in \{1, \ldots, \omega\}$ for which $K_i \neq \emptyset$. By Lemma 2, for each $i \in \Omega$ there exists a unique index $r_i$ in $K_i$ with $N(e_0 \cap e_{r_i}) = \emptyset$. Define

$$\gamma_{G_i} = - \sum_{k \in K_i} z_{k} + \sum_{k \in K_i} z_{e_k}.$$  

Then, it can be checked that

**Claim 3.** Let $z \in S_G$. Then:

(i) If $z_{u_k} = 1$ for all $k \in K_i \setminus \{r_i\}$ and $z_{e_k} = 1$ for all $k \in K_i$, then $\gamma_{G_i} = 1$;

(ii) If $z_{u_k} = z_{e_k}$ for all $k \in K_i \setminus \{r_i\}$ and $z_{e_{r_i}} = 0$, then $\gamma_{G_i} = 0$.

For notational simplicity, in the following, let $V_0 = e_0 \setminus \cup_{k \in K} e_k$. To identify the tight points of (5), we consider two cases:

(I) $z_{e_0} = 1$: a point in $S_G$ satisfies (5) tightly if and only if $\gamma_{G_i} = 1$ for all $i \in \Omega$;

(II) $z_{e_0} = 0$: a point in $S_G$ satisfies (5) tightly if and only if one of the following is satisfied:

(II') $z_v = 1$ for all $v \in V_0$, $\gamma_{G_j} = 0$ for some $j \in \Omega$ and $\gamma_{G_i} = 1$ for all $i \in \Omega \setminus \{j\}$;

(II'') $V_0 \neq \emptyset$, $z_w = 0$ for some $w \in V_0$, $z_v = 1$ for all $v \in V_0 \setminus \{w\}$, and $\gamma_{G_i} = 1$ for all $i \in \Omega$.
If $V_0 \neq \emptyset$, by part (i) of Claim 3 it is simple to check that substituting tight points of type (I) and (II') in $az \leq \alpha$, yields
\[ a_v + a_{e_0} = 0, \quad \forall v \in V_0. \tag{13} \]
Define $U_j = \cup_{k \in K_j \setminus \{r_j\}} u_k$ for all $j \in \Omega$. For each $j \in \Omega$ with $\cup_{k \in K_j} e_k \setminus U_j \neq \emptyset$, by part (ii) of Claim 3 we construct two tight points of type (II') as follows: the first tight point is obtained by letting $z_v = 0$ for all $v \in \cup_{k \in K_j} e_k$. The second tight point is obtained by letting $z_w = 1$ for some $w \in (\cup_{k \in K_j} e_k) \setminus U_j$ and $z_v = 0$ for all $v \in \cup_{k \in K_j} e_k \setminus \{w\}$. Note that from condition (1) it follows that $e_0 \cap \cup_{k \in K_j} e_k \setminus \{w\} \neq \emptyset$. By construction, in both tight points we have $z_{u_k} = z_{e_k} = 0$ for all $k \in K_j \setminus \{r_j\}$ and $z_{e_{r_j}} = 0$. Substituting these two points in $az \leq \alpha$ and subtracting the resulting expressions, gives $a_w = 0$. Using a similar line of arguments for each $w \in (\cup_{k \in K_j} e_k) \setminus U_j$ and each $j \in \Omega$, we obtain
\[ a_v = 0, \quad \forall v \in \bigcup_{k \in K} e_k \setminus \bigcup_{j \in \Omega} U_j. \tag{14} \]

Let $e_\ell$ denote a leaf of $E(\tilde{G}_j)$. We claim that $e_0 \cap e_\ell \setminus U_j$ is nonempty. If $U_j = \emptyset$, then the statement is trivial. Otherwise, by definition of a leaf $e_0 \cap e_\ell \setminus U_j \supseteq e_0 \cap e_\ell \setminus e_0 \cap e_h$ for some $h \in K_j$ such that $h \neq \ell$. Moreover, from condition (2) it follows that $e_0 \cap (e_\ell \setminus e_h) \neq \emptyset$. Now we construct two tight points as follows: the first point is a tight point of type (I). The second point is obtained by letting $z_w = 0$ for some $w \in e_0 \cap e_\ell \setminus U_j$ and $z_v = 1$ for all $v \in \cup_{k \in K_j} e_k \setminus \{w\}$. This point is a tight point of type (II'). To see this, consider a running intersection ordering of $\tilde{E}$ in which $e_0 \cap e_\ell$ is the first element. Note that by part (ii) of Lemma 1 such an ordering exists. It then follows that at this tight point we have $z_{u_k} = z_{e_k} = 1$ for all $k \in K_j \setminus \{\ell\}$ and $z_{e_\ell} = 0$. By (13), we have $a_w = 0$. Substituting these two points in $az \leq \alpha$ and subtracting the resulting relations we obtain
\[ a_{e_k} + a_{e_0} = 0, \quad \forall k \in \tilde{E} : e_k \text{ is a leaf of } \tilde{E}. \tag{15} \]

Again consider a tight point of type (II') in which $\gamma_{\tilde{G}_j} = 0$ for some $j \in \Omega$ by letting $z_{e_k} = 0$ for all $k \in K_j$ and $z_{u_k} = 0$ for all $k \in K_j \setminus \{r_j\}$. Consider a node $w$ in the set $U_j$ defined above. Denote by $K'$ the index set of all edges in $K_j$ with $e_k \supseteq w$. Let $\ell \in K'$ and consider a running intersection ordering of $\tilde{E}$ in which $e_0 \cap e_\ell$ is the first element. The existence of such an ordering follows from part (ii) of Lemma 1. Now, construct a second tight point of type (II') in which we have $z_w = 1$. By condition (3), we have $u_k = w$ for all $k \in K' \setminus \{\ell\}$, as by construction, $N(e_0 \cap e_k) \supseteq w$ for all $k \in K' \setminus \{\ell\}$. Moreover, by condition (2), there exists a node $u_\ell \in e_0 \cap (e_\ell \setminus \cup_{k \in K' \setminus \{\ell\}} e_k)$. It then follows that by letting $z_{v_\ell} = 0$ and $z_w = 1$, we can construct a tight point of type (II') in $\tilde{S}_G$ such that $z_{e_\ell} = 0$, $z_{u_k} = z_{e_k} = 1$ for all $k \in K' \setminus \{\ell\}$ and $z_{u_k} = z_{e_k} = 0$ for all $k \in K_j \setminus K'$. Substituting these two points in $az \leq \alpha$ and using (14), yields
\[ (|K'| - 1)a_w + \sum_{k \in K' \setminus \{\ell\}} a_{e_k} = 0, \quad \forall \ell \in K'. \]

It then follows that for each $w \in U$ we have
\[ a_w + a_{e_k} = 0, \quad \forall k \in \tilde{E} \text{ such that } e_k \supseteq w. \tag{16} \]

Together with (15), this implies that
\[ a_{e_k} + a_{e_0} = 0, \quad \forall k \in \tilde{E}. \tag{17} \]
Finally, by substituting the tight point of type (I) we get $\alpha = \sum_{p \in V \cup E} a_p$. Together with (13), (14), (16), (17), this implies that $az \leq \alpha$ coincides with inequality (5) up to a positive scaling, implying that (5) defines a facet of $\text{MP}_G$. □
In particular, Proposition 4 implies the following:

**Corollary 2.** Consider a running intersection inequality centered at $e_0$ with neighbors $e_k$, $k \in K$. Suppose that $|e_0 \cap e_k| \geq 2$ for all $k \in K$ and $|e_0 \cap e_k \cap e_{k'}| \leq 1$ for all $k, k' \in K$. Then this inequality defines a facet of the multilinear polytope of its support hypergraph.

**Proof.** To prove the statement it suffices to show conditions (2) and (3) of Proposition 4 are satisfied. First consider condition (2); since $|e_0 \cap e_k \cap e_{k'}| \leq 1$ for all $k, k' \in K$, it follows that for any $K' \subseteq K$, the set $e_0 \cap (\cap_{k \in K'} e_k)$ consists of at most a single node. Moreover, if $e_0 \cap (\cap_{k \in K'} e_k) = \{v\}$, then $e_0 \cap e_k \cap e_{k'} = \{v\}$ for all $k, k' \in K'$. Hence, for each $i \in K'$ we have $e_0 \cap (e_i \setminus \cup_{k \in K \setminus \{i\}} e_k) = (e_0 \cap e_i) \setminus \{v\}$, and the latter is nonempty as by assumption $|e_0 \cap e_i| \geq 2$. Condition (3) is satisfied as the assumption $|e_0 \cap e_k \cap e_{k'}| \leq 1$ for all $k, k' \in K$ implies that $|N(e_0 \cap e_k)| \leq 1$ for all $k \in K$.

We should remark that the converse of Proposition 4 does not hold in general; namely, while by Proposition 3 condition (1) is necessary, one can construct facet-defining inequalities that do not satisfy conditions (2) and (3). In fact, in Example 1 inequalities (7) are facet-defining but they do not satisfy condition (3) of Proposition 4. We believe that a complete characterization for facetness of running intersection inequalities depends on the precise structure of the support hypergraph.

### 2.5 Computational impact

In [15], the authors demonstrate the effectiveness of running intersection inequalities in constructing strong polyhedral relaxations for general multilinear polytopes. Namely, they devise an efficient algorithm for separating running intersection inequalities which they embed at every node of the branch-and-reduce global solver BARON [20]. Results for multilinear and polynomial optimization problems of degree three and four show that running intersection cuts significantly improve the performance of BARON.

As we detailed before running intersection inequalities serve as a generalization of flower inequalities [13]. Indeed, running intersection cuts have a more complex form than flower cuts and the corresponding proof techniques are more involved. In the following we demonstrate the significance of running intersection cuts in global optimization via a simple numerical study. We consider a test set containing computer vision instances from an image restoration problem. This test set consists of 45 unconstrained binary polynomial optimization problems of degree four. See [11] for the problem formulation and the detailed description of the test set. It can be checked that corresponding hypergraphs are not $\beta$-acyclic. To highlight the benefits of running intersection cuts, we devise two relaxation construction strategies. We utilize the cut generation scheme of [15] to add (i) running intersection cuts and (ii) only flower cuts to BARON’s polyhedral relaxation. We compare the root-node relaxation gap, defined as the difference between the upper and lower bounds for the problem at the root node of the tree for the two relaxation strategies. We call a problem trivial, if it is solved to global optimality at the root node by both algorithms. Out of 45 problems 10 were trivial. Results for the nontrivial problems are shown in Figure 2.5. For 27 instances, i.e., for about 80% of the problems, running intersection cuts result in more than 95% reduction in root node relaxation gap. This experiment demonstrate the usefulness of these inequalities in their most general form.

### 3 Convex hull characterizations

In [13], we defined the flower relaxation as the polytope obtained by adding all flower inequalities for a multilinear set to its standard linearization. Subsequently, we showed that the flower relaxation
Lemma 3. Let $G = (V, E)$ be a hypergraph. If the subhypergraph $G_{V'}$ contains a $\beta$-cycle of length $t$, then $G$ contains a $\beta$-cycle of length $t$. In particular, if $G$ is $\beta$-acyclic, then $G_{V'}$ is $\beta$-acyclic as well.

Proof. Suppose that $G_{V'}$ contains a $\beta$-cycle $v_1, v_1', v_2, v_2', \ldots, v_t, v_t'$. It is simple to check that $v_1, v_1', v_2, v_2', \ldots, v_t, v_t'$ is a $\beta$-cycle in $G$. \qed
The following result, first appeared in [4], relates the concepts of $\beta$-acyclicity and running intersection property.

**Lemma 4.** A hypergraph $G = (V, E)$ is $\beta$-acyclic if and only if every $E' \subseteq E$ has the running intersection property.

### 3.2 A necessary condition for the tightness of the running intersection relaxation

Denote by $R$ a relaxation of the Multilinear set; namely, $R$ is a function that associates to each hypergraph $G$ a set $R_G$ containing all points in $S_G$. Consider a hypergraph $G = (V, E)$ and let $\tilde{V}$ be a subset of $V$. Define

$$L_{\tilde{V}} := \{z \in \mathbb{R}^{V+E} : z_v = 1 \forall v \in V \setminus \tilde{V}\}. \tag{18}$$

Denote by $\text{proj}_{G_{\tilde{V}}}(R_G \cap L_{\tilde{V}})$ the set obtained from $R_G \cap L_{\tilde{V}}$ by projecting out all variables $z_v$, for all $v \in V \setminus \tilde{V}$, and $z_f$, for all $f \in E \setminus \{e'(e) : e \in E(G_{\tilde{V}})\}$. In [13] we showed the following equivalence for the Multilinear polytope:

**Lemma 5.** Let $G = (V, E)$ be a hypergraph and let the set $L_{\tilde{V}}$ be defined by (18) for some $\tilde{V} \subseteq V$. Then $MP_{G_{\tilde{V}}} = \text{proj}_{G_{\tilde{V}}}(MP_G \cap L_{\tilde{V}})$.

Next, we present a weaker version of the this result for the running intersection relaxation. We state this result without a proof, as the proof is a straightforward generalization of the proof of Lemma 13 in [13] wherein we show that a similar inclusion relation holds for the flower relaxation.

**Lemma 6.** Let $G = (V, E)$ be a hypergraph and let the set $L_{\tilde{V}}$ be defined by (18) for some $\tilde{V} \subseteq V$. Then $MP_{RI_{G_{\tilde{V}}}} \subseteq \text{proj}_{G_{\tilde{V}}}(MP_{RI_G} \cap L_{\tilde{V}})$.

The following proposition provides a necessary condition for the tightness of the running intersection relaxation.

**Proposition 5.** If the hypergraph $G$ is not $\beta$-acyclic, then $MP_G \subset MP_{RI_G}$.

**Proof.** Suppose that $G$ contains at least one $\beta$-cycle. Denote by $C$ a $\beta$-cycle of minimum length, say $t$. To show that $MP_G \subset MP_{RI_G}$, by Lemma 5 and Lemma 6 it is sufficient to prove that $MP_{G_{V(C)}} \subset MP_{RI_{G_{V(C)}}}$.

Define the set $\tilde{E} := \{e \cap V(C) : e \in E(C)\}$. Clearly, $\tilde{E} \subseteq E(G_{V(C)})$. First suppose that $\tilde{E} = E(G_{V(C)})$; i.e., $G_{V(C)}$ is a graph that consists of a chordless cycle. The inclusion $MP_{G_{V(C)}} \subset MP_{RI_{G_{V(C)}}}$ is then valid as the odd-cycle inequalities are facet-defining for $MP_{G_{V(C)}}$ [25] and are clearly not implied by $MP_{RI_{G_{V(C)}}}$.

Next, suppose that $\tilde{E} \subset E(G_{V(C)})$. Let $\tilde{e}$ be in $E(G_{V(C)}) \setminus \tilde{E}$. We claim that $\tilde{e} = V(C)$. To obtain a contradiction, suppose that $\tilde{e} \subset V(C)$. Then it is simple to check that $G_{V(C)}$ contains a $\beta$-cycle of length $t'$ with $t' < t$. By Lemma 3 also $G$ contains a $\beta$-cycle of length $t'$. However, this contradicts the assumption that $C$ is $\beta$-cycle of $G$ of minimum length. Hence $\tilde{e} = V(C)$. This shows that $E(G_{V(C)}) = \tilde{E} \cup V(C)$, i.e., the hypergraph $G_{V(C)}$ consists of a chordless cycle enclosed by the edge $\tilde{e}$. Denote by $az \leq \alpha$ an odd-cycle inequality corresponding to the chordless cycle in $G_{V(C)}$. Suppose that $a_e = -1$ for $e \in M \subseteq E(C)$ such that $|M| = 2h + 1$ for some $h \geq 1$. It can be checked that any inequality of the form $az + hze \leq \alpha$ defines a facet of $MP_{G_{V(C)}}$. However, such inequalities are not present in $MP_{RI_{G_{V(C)}}}$. Consequently, if the hypergraph $G$ contains a $\beta$-cycle, we have $MP_{G_{V(C)}} \subset MP_{RI_{G_{V(C)}}}$. \qed
Henceforth, we consider a $\beta$-acyclic hypergraph $G = (V, E)$. By Lemmata 1 and 3, given any edge $e_0 \in E$ and a collection of adjacent edges $e_k$, $k \in K$, the set $\{e_0 \cap e_k : k \in K\}$ has the running intersection property. Hence, the polytope $\text{MP}^\text{RI}_G$ can be simply obtained by adding to $\text{MP}^\text{LP}_G$ all inequalities of the form (5) with any $e_0 \in E$ as the center edge and any collection of adjacent edges $e_k$, $k \in K$. The following example indicates that even for $\beta$-acyclic hypergraphs, the running intersection relaxation may not coincide with the multilinear polytope.

**Example 2.** Consider the hypergraph $G = (V, E)$ with $V = \{v_1, v_2, v_3, v_4\}$ and $E = \{e_{12}, e_{123}, e_{124}, e_{1234}\}$, where the edge $e_1$ contains the nodes with indices in $I$. It is simple to check that $G$ is $\beta$-acyclic. It can be shown that the inequality $-z_{e_{12}} + z_{e_{123}} + z_{e_{124}} - z_{e_{1234}} \leq 0$ defines a facet of $\text{MP}_G$ and is not valid for the running intersection relaxation of $\text{S}_G$. \(\diamondsuit\)

More generally, it can be checked that the multilinear polytope of $\beta$-acyclic hypergraphs can have dense facet-defining inequalities. By dense facets, we mean facets whose support hypergraph contains almost all edges of the original hypergraph. This is in major contrast with the support hypergraph of running intersection inequalities which consists of a center edge that is adjacent to all other edges. In the following, we characterize a class of $\beta$-acyclic hypergraphs for which we have $\text{MP}_G = \text{MP}^\text{RI}_G$. We believe that for general $\beta$-acyclic hypergraphs $\text{MP}_G$ has a far more complicated facial structure than $\text{MP}^\text{RI}_G$.

### 3.3 A sufficient condition for the tightness of the running intersection relaxation

We now introduce the class of kite-free $\beta$-acyclic hypergraphs. As we will show in the following, for this class of hypergraphs the running intersection relaxation coincides with the multilinear polytope.

A **kite** in a hypergraph $G = (V, E)$ consists of three edges $e_0, e_1, e_2 \in E$ such that $|e_0 \cap e_1 \cap e_2| \geq 2$, $(e_0 \cap e_1) \setminus e_2 \neq \emptyset$, and $(e_0 \cap e_2) \setminus e_1 \neq \emptyset$. See Figure 4(a) for an illustration of a kite. A hypergraph $G = (V, E)$ is said to be kite-free if it contains no kite. See Figure 4(b) for an example of a kite-free $\beta$-acyclic hypergraph. The hypergraph in Example 2 is $\beta$-acyclic but is not kite-free; that is, it contains a kite consisting of edges $\{v_1, v_2, v_3\}, \{v_1, v_2, v_4\}, \{v_1, v_2, v_4\}$.

As we mentioned before, a polynomial-time algorithm for determining $\beta$-acyclicity of hypergraphs is available [18]. Moreover, one can check in $O(|E|^3)$ operations whether a hypergraph $G = (V, E)$ is kite-free; hence, the detection problem for kite-free $\beta$-acyclic hypergraphs runs in polynomial-time.

![Figure 4](image-url)

**Figure 4:** (a) An illustration of a kite, (b) a kite-free $\beta$-acyclic hypergraph.

As we detail in the following, if $G$ is a kite-free $\beta$-acyclic hypergraph, then the subhypergraph $G_e$ of $G$ induced by any edge $e \in E(G)$ has a particular structure that enables us to characterize $\text{MP}_{G_e}$ using a lift-and-project technique. Let us first define a $t$-laminar hypergraph. A hypergraph...
Let \( G = (V, E) \) be \( t \)-laminar if for any two edges \( e_1, e_2 \in E \) with \(|e_1 \cap e_2| \geq t \), we have \( e_1 \subset e_2 \) or \( e_2 \subset e_1 \) (see [17] for more details on \( t \)-laminarity). In particular, 1-laminar hypergraphs are referred to as laminar hypergraphs. The following is the key connection between kite-free hypergraphs and 2-laminar hypergraphs.

**Lemma 7.** Let \( G \) be a kite-free hypergraph, and let \( e_0 \in E(G) \). Then the subhypergraph \( G_{e_0} \) of \( G \) induced by \( e_0 \) is a 2-laminar hypergraph.

**Proof.** Assume by contradiction that \( G_{e_0} \) is not 2-laminar. Then there exist two edges \( e_1, e_2 \) of \( G \) such that \(|\{e_0 \cap e_1\} \cap \{e_0 \cap e_2\}| \geq 2 \), \( e_0 \cap e_1 \not\supseteq e_0 \cap e_2 \), and \( e_0 \cap e_2 \not\supseteq e_0 \cap e_1 \). Then edges \( e_0, e_1, e_2 \) satisfy \(|e_0 \cap e_1 \cap e_2| \geq 2 \), \( (e_0 \cap e_1) \setminus e_2 = (e_0 \cap e_1) \setminus (e_0 \cap e_2) \not= \emptyset \), and \( (e_0 \cap e_2) \setminus e_1 = (e_0 \cap e_2) \setminus (e_0 \cap e_1) \not= \emptyset \). This contradicts the fact that \( G \) is kite-free.

The running intersection inequalities (6) can be greatly simplified if \( G \) is a kite-free \( \beta \)-acyclic hypergraph. Consider a collection of edges \( e_0, e_k, k \in K \), satisfying conditions (i) and (ii) of Proposition 3, i.e., \( e_0 \cap e_k \not\supseteq e_0 \cap e_{k'} \) for any \( k, k' \in K \), and \(|e_0 \cap e_k| \geq 2 \) for all \( k \in K \). By construction, \( \hat{G} = (e_0, \hat{E}) \), where \( \hat{E} \) is defined by (4), is a partial hypergraph of the subhypergraph of \( G \) induced by \( e_0 \). Hence, by Lemma 7 \( \hat{G} \) is a 2-laminar hypergraph; it then follows that each set \( N(e_0 \cap e_k), k \in K \), as defined by (3) consists of at most a single node. For each node \( v \in e_0 \), denote by \( \delta_K(v) \) the number of edges in \( e_k, k \in K \), that contain \( v \). Then, there exists only one running intersection inequality centered at \( e_0 \) with neighbors \( e_k, k \in K \), and it can be checked that this inequality is of the form

\[
\sum_{v \in e_0} (1 - \delta_K(v)) z_v + \sum_{k \in K} z_{e_k} - z_{e_0} \leq \omega - 1,
\]

where, as before \( \omega \) denotes the number of connected components of \( \hat{G} \).

In the remainder of this section we state the results that we need to establish that the multilinear polytope of kite-free \( \beta \)-acyclic hypergraphs coincides with the running intersection relaxation. To streamline the presentation, the technical proofs are given in Section 3.3.1. In Section 3.3.1 we characterize the multilinear polytope of 2-laminar \( \beta \)-acyclic hypergraphs using a lift-and-project type technique. Subsequently, in Section 3.3.2 we present a sufficient condition under which a multilinear set is decomposable into a collection of simpler multilinear sets. In Section 3.3.3 we employ the results of Sections 3.3.1 and 3.3.2 to obtain a compact extended formulation for \( \text{MP}_G \). More precisely, we show that in a lifted space, the multilinear polytope of a kite-free \( \beta \)-acyclic hypergraph \( G \) is representable as the intersection of a collection of multilinear polytopes of 2-laminar \( \beta \)-acyclic hypergraphs. Finally, in Section 3.3.4 by projecting out the extra variables we show that in the original space we have \( \text{MP}_G = \text{MP}^{\beta 1/2}_G \).

### 3.3.1 The multilinear polytope of 2-laminar \( \beta \)-acyclic hypergraphs

By definition, a laminar hypergraph is also 2-laminar. However, while laminarity implies \( \gamma \)-acyclicity, a 2-laminar \( \beta \)-acyclic hypergraph contains \( \gamma \)-cycles in general, resulting in an increased complexity of the corresponding multilinear polytope. In [14], we showed that the subhypergraph induced by an edge of a \( \gamma \)-acyclic hypergraph is laminar. Subsequently, we characterized the multilinear polytope of laminar hypergraphs by leveraging on a fundamental result due to Conforti and Cornuéjols regarding the connection between integral polyhedra and balanced matrices [9]. Namely, we showed that the constraint matrix corresponding to the facet description of the multilinear polytope of laminar hypergraphs is balanced. A similar proof technique is not applicable to 2-laminar \( \beta \)-acyclic hypergraphs as the concept of balancedness is only defined for \( 0, \pm 1 \) matrices;
that is, such a technique can only be used if the constraint matrix corresponding to the facet description of the multilinear polytope only contains 0, \pm 1 entries. However, for 2-laminar \(\beta\)-acyclic hypergraphs, some facet-defining inequalities have general integer-valued coefficients. We employ a lift-and-project type argument to characterize the multilinear polytope of these hypergraphs, which is significantly more involved than our earlier proof for laminar hypergraphs.

To state the facet-description of \(\text{MP}_G\) for a 2-laminar \(\beta\)-acyclic hypergraph \(G = (V, E)\), we make use of the following notation. For each edge \(e \in E\), define \(I(e) := \{p \in V \cup E : p \subseteq e, p \not\subset e'\text{ for } e' \in E, e' \subset e\}\) and denote by \(\omega(e)\) the number of connected components in the hypergraph \(H_e = (e, I(e) \cap E)\). For each \(v \in V\), let \(\delta_e(v)\) denote the number of edges in \(H_e\) containing \(v\). It is simple to show that \(\omega(e) = \sum_{v \in e} (1 - \delta_e(v)) + |I(e) \cap E|\).

**Proposition 6.** Let \(G = (V, E)\) be a 2-laminar \(\beta\)-acyclic hypergraph. Then \(\text{MP}_G\) is described by the following system:

\[
\begin{align*}
 z_v &\leq 1 & &\forall v \in V \\
 -z_p &\leq 0 & &\forall p \in V \cup E \text{ s.t. } p \not\subset f, \text{ for every } f \in E \tag{20} \\
 -z_p + z_e &\leq 0 & &\forall e \in E, \forall p \in I(e) \\
 \sum_{v \in e} (1 - \delta_e(v))z_v &+ \sum_{p \in I(e) \cap E} z_p - z_e &\leq \omega(e) - 1 &\forall e \in E.
\end{align*}
\]

The proof of Proposition 6 is given in Section 5.1.

Consider the inequalities of system (20). Clearly, the first two sets are present in \(\text{MP}^\text{LP}_G\). The third set is present in \(\text{MP}^\text{LP}_G\) if \(p\) is a node, and is a running intersection inequality if \(p\) is an edge. Finally, for each \(e \in E\), the last inequality is present in \(\text{MP}^\text{LP}_G\) if \(I(e) \subset V\) and is a running intersection inequality otherwise. Hence, we have the following characterization:

**Corollary 3.** Let \(G\) be a 2-laminar \(\beta\)-acyclic hypergraph. Then \(\text{MP}_G = \text{MP}^\text{RI}_G\).

It is important to note that for a 2-laminar \(\beta\)-acyclic hypergraph \(G\), the relaxation \(\text{MP}^\text{RI}_G\) in general contains many more running intersection inequalities than system (20). More precisely, for each edge \(e \in E(G)\), inequalities (20) contain at most two running intersection inequalities in which \(e\) is the center edge, while in the description of \(\text{MP}^\text{RI}_G\), the number of running intersection inequalities (19) centered at \(e\) grows exponentially with the number of neighbors. In addition, it can be shown that all running intersection inequalities in system (20) are facet-defining, whereas many of the running intersection inequalities present in \(\text{MP}^\text{RI}_G\) are redundant and identifying such redundant inequalities is not simple in general. This compact representation is the key property of 2-laminar \(\beta\)-acyclic hypergraphs which enables us to employ a lift-and-project technique to directly characterize their multilinear polytope.

### 3.3.2 A sufficient condition for decomposability of multilinear sets

Given hypergraphs \(G_\alpha = (V_\alpha, E_\alpha)\) and \(G_\omega = (V_\omega, E_\omega)\) we denote by \(G_\alpha \cap G_\omega\) the hypergraph \((V_\alpha \cap V_\omega, E_\alpha \cap E_\omega)\) and by \(G_\alpha \cup G_\omega\) the hypergraph \((V_\alpha \cup V_\omega, E_\alpha \cup E_\omega)\). Let \(G\) be a hypergraph and let \(G_\alpha, G_\omega\) be section hypergraphs of \(G\) such that \(G_\alpha \cap G_\omega = G\). We say that the set \(\mathcal{S}_G\) is decomposable into the sets \(\mathcal{S}_{G_\alpha}\) and \(\mathcal{S}_{G_\omega}\) if

\[
\text{conv } \mathcal{S}_G = \text{conv } \mathcal{S}_{G_\alpha} \cap \text{conv } \mathcal{S}_{G_\omega},
\]

where \(\mathcal{S}_{G_\alpha}\) (resp. \(\mathcal{S}_{G_\omega}\)) is the set of all points in the space of \(\mathcal{S}_G\) whose projection in the space defined by \(G_\alpha\) (resp. \(G_\omega\)) is \(\mathcal{S}_{G_\alpha}\) (resp. \(\mathcal{S}_{G_\omega}\)).
In [14] and [13] we derived sufficient conditions for decomposability of multilinear sets. In [14] we showed that $S_G$ is decomposable into $S_{G_\alpha}$ and $S_{G_\omega}$ if the hypergraph $G_\alpha \cap G_\omega$ is complete. In [13] we showed that $S_G$ is decomposable into $S_{G_\alpha}$ and $S_{G_\omega}$ if $e = V(G_\alpha) \cap V(G_\omega)$ is an edge of $G$ and every edge that is only present in $G_\alpha$ either contains $e$ or is disjoint from it. In particular, our decomposition result in [13] enables us to characterize multilinear polytopes of Berge-acyclic and $\gamma$-acyclic hypergraphs by showing that the corresponding multilinear sets are decomposable into a collection of simpler subsets whose convex hulls can be obtained directly.

Next, in Theorem 1 we provide a new sufficient condition for decomposability of multilinear sets. The setting considered in Theorem 1 is significantly more involved than the ones described above. Namely, the edges of $G_\alpha$ may only contain a subset of nodes in $V(G_\alpha) \cap V(G_\omega)$, and as a result our earlier tools in [14] and [13] are not applicable to the current setting. More precisely, the key step in proving all these decomposition results is to show that a vector $(\tilde{z}_\alpha, \tilde{z}_\gamma, \tilde{z}_\omega)$ can be written as a convex combination of vectors in $S_G$ if $(\tilde{z}_\alpha, \tilde{z}_\gamma)$ can be written as a convex combination of vectors in $S_{G_\alpha}$ and $(\tilde{z}_\gamma, \tilde{z}_\omega)$ can be written as a convex combination of vectors in $S_{G_\omega}$. To prove the decomposition results in [14] and [13] it is sufficient to consider vectors in $S_G$ obtained by combining only one vector in $S_{G_\alpha}$ with only one vector in $S_{G_\omega}$. However, to prove Theorem 1 it seems no longer sufficient to consider vectors in $S_G$ obtained by combining only one vector in $S_{G_\alpha}$ with one vector in $S_{G_\omega}$. To address this issue, we exploit the special structure of $G_\alpha$ and partition its edge set into $k$ subsets based on the nodes in $V(G_\alpha) \cap V(G_\omega)$ to which they are connected. This allows us to combine one vector in $S_{G_\omega}$ with $k$ vectors in $S_{G_\alpha}$ (one per each element of the partition) that coincide in certain components of $G_\alpha \cap G_\omega$ and obtain a vector in $S_G$. Finally, we show that any vector $(\tilde{z}_\alpha, \tilde{z}_\gamma, \tilde{z}_\omega) \in MP_G$ can be written as a convex combination of the obtained vectors in $S_G$.

We now state our decomposition result. The proof is given in Section 5.2.

**Theorem 1.** Let $G$ be a hypergraph, and let $G_\alpha, G_\omega$ be section hypergraphs of $G$ such that $G_\omega \cup G_\omega = G$. Denote by $\bar{p} := V(G_\alpha) \cap V(G_\omega)$. Suppose that $\bar{p} \in V(G) \cup E(G)$ and that $G_\alpha$ is a 2-laminar $\beta$-acyclic hypergraph. Then the set $S_G$ is decomposable into $S_{G_\alpha}$ and $S_{G_\omega}$.

### 3.3.3 A compact extended formulation of $MP_G$

We now use the result of Theorem 1 to obtain a compact extended formulation for the multilinear polytope of kite-free $\beta$-acyclic hypergraphs. We say that an edge is *maximal* if it is not strictly contained in any other edge. Consider a kite-free $\beta$-acyclic hypergraph $G = (V, E)$. If $V$ is an edge of $G$, by Lemmata 3 and 7, $G$ is a 2-laminar $\beta$-acyclic hypergraph, and consequently by Corollary 3 we have $MP_G = MP_{RI}^G$. Henceforth, suppose that $G$ has at least two maximal edges. Denote by $\tilde{E}$ the set of all maximal edges of $G$, and define $\kappa := |\tilde{E}|$. Then by Lemma 4 there exists a running intersection ordering $\tilde{e} = e_1, \ldots, e_\kappa$ of $\tilde{E}$. Let the sets $N(e_j), j \in \{1, \ldots, \kappa\}$ be as defined in (3). We now construct the hypergraph $G^+ = (V, E^+)$ obtained from $G$ by adding at most $\kappa - 1$ auxiliary edges to $E$, defined as follows:

$$E^+ := E \cup \{N(e_j) : |N(e_j)| \geq 2, j \in \{2, \ldots, \kappa\}\}. \tag{21}$$

The following theorem provides an extended formulation of polynomial size for $MP_G$ which contains at most $|V| + 2|E|$ variables and $2(|V| + (r + 1)|E|)$ inequalities, where $r$ denotes the maximum cardinality of the edges of $G$. In essence, via a recursive application of our decomposition result stated in Theorem 1 we show that $S_{G^+}$ is decomposable into a collection to multilinear sets of 2-laminar $\beta$-acyclic hypergraphs.
Theorem 2. Let $G = (V, E)$ be a kite-free $\beta$-acyclic hypergraph. Denote by $\bar{e}_i$, $i = 1, \ldots, \kappa$, the maximal edges of $G$. Consider the hypergraph $G^+ = (V, E^+)$, where $E^+$ is defined by (21), and denote by $G_i^+$, $i = 1, \ldots, \kappa$, the section hypergraph of $G^+$ induced by $\bar{e}_i$. Then $G_i^+$, $i \in \{1, \ldots, \kappa\}$, is a 2-laminar $\beta$-acyclic hypergraph and

$$MP_{G^+} = \bigcap_{i=1}^{\kappa} MP_{G_i^+}. \quad (22)$$

Proof. Consider a kite-free $\beta$-acyclic hypergraph $G = (V, E)$. By Lemma 4 there exists a running intersection ordering $\mathcal{O} = \bar{e}_1, \ldots, \bar{e}_\kappa$ of the set of maximal edges of $G$. Let $G_{\bar{e}_\kappa}$ denote the sub-hypergraph of $G$ induced by $\bar{e}_\kappa$. Since $G$ is a kite-free $\beta$-acyclic hypergraph, by Lemmata 3 and 7 $G_{\bar{e}_\kappa}$ is a 2-laminar $\beta$-acyclic hypergraph. Now consider the hypergraph $G^+ = (V, E^+)$, where $E^+$ is defined by (21). We define $G_\alpha^1$ as the section hypergraph of $G^+$ induced by $\bar{e}_\kappa$, and $G_\omega^1$ as the section hypergraph of $G^+$ induced by $\bigcup_{E \in \mathcal{O}} (G_\alpha^1 e)$. It is simple to check that $G_\alpha^1$ is a partial hypergraph of $G_{\bar{e}_\kappa}$. Hence, $G_\alpha^1$ is a 2-laminar $\beta$-acyclic hypergraph as well. In addition, both $G_\alpha^1$ and $G_\omega^1$ are different from $G^+$ and we have $G_\alpha^1 \cup G_\omega^1 = G^+$, $G_\alpha^1 \cap G_\omega^1 = N(\bar{e}_\kappa)$, where the set $N(\bar{e}_\kappa)$ is defined in (3). Finally, by construction, $N(\bar{e}_\kappa) \in E^+$. Thus all assumptions of Theorem 1 are satisfied and the set $S_{G^+}$ is decomposable into $S_{G_\alpha^1}$ and $S_{G_\omega^1}$. As $G_\alpha^1$ is a 2-laminar $\beta$-acyclic hypergraph, $MP_{G_\alpha^1}$ is given by Proposition 6.

Now define $G_{\bar{e}_\kappa} := G_{\bar{e}_{\kappa-1}}$ and consider the edge $\bar{e}_{\kappa-1}$, that is, the element of $\mathcal{O}$ before $\bar{e}_\kappa$. Let $G_{\bar{e}_{\kappa-1}}$ denote the sub-hypergraph of $G$ induced by $\bar{e}_{\kappa-1}$. Again, by Lemmata 3 and 7, $G_{\bar{e}_{\kappa-1}}$ is a 2-laminar $\beta$-acyclic hypergraph. Define $G_\alpha^2$ as the section hypergraph of $G_{\bar{e}_\kappa}^+$ induced by $\bar{e}_{\kappa-1}$ and $G_\omega^2$ as the section hypergraph of $G_{\bar{e}_\kappa}^+$ induced by $\bigcup_{E \in \mathcal{O}} (G_\alpha^2 e)$. The hypergraph $G_\alpha^2$ is a partial hypergraph of $G_{\bar{e}_{\kappa-1}}$ and as a result is a 2-laminar $\beta$-acyclic hypergraph as well. Similarly, we can verify that all assumptions are Theorem 1 are satisfied and the set $S_{G_{\bar{e}_\kappa}^+ \backslash \kappa}$ is decomposable into $S_{G_\alpha^2}$ and $S_{G_\omega^2}$. By a recursively application of this argument for all elements of $\mathcal{O}$ in the reverse order, we conclude that the multilinear set $S_{G^+}$ is decomposable into the sets $S_{G_i^+}$, $i = 1, \ldots, \kappa$, where $G_i^+$ is the section hypergraph of $G^+$ induced by $\bar{e}_{\kappa-i+1}$, which as detailed above is a 2-laminar $\beta$-acyclic hypergraph with the corresponding multilinear polytope given by Proposition 6.

In particular, Theorem 2 implies that we can optimize over $MP_G$ in polynomial time.

3.3.4 The explicit characterization of $MP_G$

The facet description of each polytope $MP_{G_i^+}$ in (22) is given by system (20) in Proposition 4. By projecting out the auxiliary variables $z_e$, $e \in E^+ \setminus E$, from the description of $MP_{G^+}$, using Fourier-Motzkin elimination, we obtain an explicit characterization for $MP_G$.

Theorem 3. Let $G$ be a kite-free $\beta$-acyclic hypergraph. Then $MP_G = MP_G^{RI}$. \hfill \Box

The proof of Theorem 3 is given in Section 5.3.

It is important to note that while Theorem 3 provides an explicit description of $MP_G$ in the original space, the polytope $MP_G^{RI}$ may contain exponentially many facet-defining inequalities in general (see Example 2 in [14] in which we gave a $\gamma$-acyclic hypergraph $G$ for which the number of facets of $MP_G$ is not bounded by a polynomial in $|V(G)|$ and $|E(G)|$). From Theorems 2 and 3 it follows that if $G$ is a kite-free $\beta$-acyclic hypergraph, we can optimize over $MP_G$ in polynomial time. By the equivalence of separation and optimization, for this class of hypergraphs, the separation problem over $MP_G$ can be solved in polynomial time as well. In fact, our results imply that separation over $MP_G$ can be done in a simple way which does not rely on the ellipsoid algorithm. Namely,
given a vector \( \tilde{z} \in \mathbb{R}^{V+E} \), one can substitute \( \tilde{z} \) in the system defining \( MP_{G^+} \) in Theorem 2 and obtain a system of linear inequalities only involving extended variables. Via linear programming, we can solve the feasibility problem over the reduced system. If this system is feasible, then clearly \( \tilde{z} \in MP_{G^+} \). Otherwise, Farkas’ lemma provides a certificate of infeasibility which can be used to construct an inequality that separates \( \tilde{z} \) from \( MP_{G^+} \).

We conclude this section by remarking that the converse of Theorem 3 is not correct, in general. Obtaining a complete characterization of \( \beta \)-acyclic hypergraphs for which the running intersection relaxation coincides with the multilinear polytope is a topic of future research.

4 Connections with the treewidth based approach

In this section we investigate the connections between our convex hull characterization and an earlier result in the literature that relates the complexity of \( MP_G \) to the treewidth of the intersection graph of \( G \) [27, 22, 6]. We refer the reader to [6] for the standard definition of treewidth. Recall that the intersection graph of a hypergraph \( G = (V,E) \) is the graph \( U = (V,E') \) where \( \{i,j\} \in E' \) if and only if there exists \( e \in E \) with \( \{i,j\} \subseteq e \). The next theorem follows from the results presented in [27, 22, 6]. In these papers, the authors give an extended formulation for the convex hull of the feasible set of (possibly) constrained binary polynomial optimization problems. As in our setting the multilinear polytope corresponds to the convex hull of the feasible set of an unconstrained binary polynomial optimization problem, we state their result for the unconstrained case.

**Theorem 4.** Let \( G = (V,E) \) be a hypergraph, and let \( w \) be the treewidth of its intersection graph. Then there exists an extended formulation of \( MP_G \) with \( O(2^w|V|) \) variables and constraints.

We now present a result that is equivalent to Theorem 4 and relates the complexity of \( MP_G \) to its hypergraph acyclicity. This alternative statement in turn enables us to directly compare Theorem 4 with our result stated in Theorem 2. Recall that the rank of a hypergraph \( G = (V,E) \) is the maximum cardinality of an edge in \( E \).

**Theorem 5.** Let \( G = (V,E) \) be an \( \alpha \)-acyclic hypergraph of rank \( r \). Then there exists an extended formulation of \( MP_G \) with \( O(2^r-1|V|) \) variables and constraints.

By Theorem 5 the multilinear polytope of an \( \alpha \)-acyclic hypergraph with constant rank has an extended formulation of polynomial size. As we mentioned before, \( \alpha \)-acyclic hypergraphs are the most general type of acyclic hypergraphs. Several equivalent definitions of \( \alpha \)-acyclic hypergraphs are known. In the following, we will use the characterization stated in Lemma 8 below, which can be obtained with little effort from Theorem 3.4 in [4]. Before stating this lemma, we recall a couple of graph theoretic concepts. A hypergraph \( G \) is conformal if for every clique \( K \) in its intersection graph, there is an edge of \( G \) that contains \( K \). A graph is chordal if every cycle with at least four distinct nodes has a chord.

**Lemma 8.** A hypergraph \( G \) is \( \alpha \)-acyclic if and only if its intersection graph \( U \) is chordal, and the set of maximal cliques of \( U \) coincides with the set of maximal edges of \( G \).

**Proof.** Let \( G \) be a hypergraph and let \( U \) be its intersection graph. From Theorem 3.4 (1) \( \Leftrightarrow \) (3) in [4] we know that \( G \) is \( \alpha \)-acyclic if and only if it is conformal and \( U \) is chordal. Therefore, it suffices to show that the following two conditions are equivalent: (a) \( G \) is conformal; (b) the set of maximal cliques of \( U \) coincides with the set of maximal edges of \( G \).

Clearly (b) implies (a), thus in the remainder of the proof we show that (a) implies (b). Let \( G' \) be obtained from \( G \) by removing from \( E \) each edge that is a proper subset of another edge.
Clearly, in \( G' \) no edge is a proper subset of another edge. Note that \( U \) is the intersection graphs of both \( G \) and \( G' \). The hypergraph \( G' \) is also conformal. In fact, since \( G \) is conformal, for every clique \( K \) in \( U \) there is an edge \( e \) of \( G \) that contains \( K \). By definition of \( G' \), there is an edge \( e' \) of \( G' \) that contains \( e \). Therefore \( K \subseteq e' \) and so \( G' \) is conformal. Since \( G' \) is conformal and no edge of \( G' \) is a proper subset of another edge, from Theorem 3.2 in \footnote{1} we know that the edges of \( G' \) are precisely the maximal cliques of \( U \). But the edges of \( G' \) coincide with the maximal edges of \( G \). This concludes the proof that (a) implies (b), and hence the lemma holds. \( \square \)

The following two Lemmata enable us to prove the equivalence of Theorem \footnote{3} and Theorem \footnote{5}

\textbf{Lemma 9.} Let \( G \) be an \( \alpha \)-acyclic hypergraph of rank \( r \). Then the intersection graph of \( G \) has treewidth \( r - 1 \).

\textit{Proof.} Let \( G \) be a hypergraph as defined in the statement, and let \( U \) be its intersection graph. From Lemma \footnote{8} it follows that \( U \) is chordal and the set of maximal cliques of \( U \) coincides with the set of maximal edges of \( G \). Since \( U \) is chordal, the treewidth of \( U \) is one less than the cardinality of the largest clique in \( U \) (see, e.g., \footnote{19}). Therefore, the treewidth of \( U \) is one less than the cardinality of the largest edge of \( G \), that is, \( r - 1 \). \( \square \)

\textbf{Lemma 10.} Let \( G \) be a hypergraph, and let \( w \) be the treewidth of its intersection graph. Then \( G \) is a partial hypergraph of an \( \alpha \)-acyclic hypergraph \( G' \) of rank \( w + 1 \).

\textit{Proof.} Let \( G = (V, E) \) be a hypergraph, let \( U \) be its intersection graph, and assume that \( U \) has constant treewidth. We refer the reader to \footnote{6} for the standard definitions of tree decomposition, width, and treewidth. Let \( V = \bigcup_{t \in T} W_t \) be a tree decomposition of \( U \) of minimum width, and let \( G' \) be the hypergraph defined by \( G' := (V, E \cup \{W_t : t \in T\}) \). Clearly \( G \) is a partial hypergraph of \( G' \). We show that each edge of \( G' \) contains at most \( w + 1 \) nodes. Since by assumption, the width of the tree decomposition \( V = \bigcup_{t \in T} W_t \) of \( U \) is \( w \), it follows that \( \max\{|W_t| : t \in T\} = w + 1 \). By definition of intersection graph, each \( e \in E \) is a clique in \( U \). It is well-known that each clique in \( U \) is contained in a set \( W_t \), for \( t \in T \) (see Lemma 2.2 in \footnote{19}). Therefore, each \( e \in E \) contains at most \( w + 1 \) nodes. This completes the proof that \( G' \) has rank \( w + 1 \).

Next, we show that \( G' \) is \( \alpha \)-acyclic. Let \( U' \) be the intersection graph of \( G' \). By Lemma \footnote{8} it suffices to show that \( U' \) is chordal, and that the set of maximal cliques of \( U' \) coincides with the set of maximal edges of \( G' \). Note that \( U' \) is obtained by adding edges to \( U \) so that each \( W_t \) becomes a clique. This implies that \( U' \) is chordal (see Lemma 5.16 in \footnote{19}). Furthermore, each clique in \( U' \) is contained in a set \( W_t \), for \( t \in T \), which is an edge of \( G' \). Vice versa, we have already seen that each edge of \( G' \) is contained in a set \( W_t \), and so it is contained in a clique in \( U' \). Therefore, the set of maximal cliques of \( U' \) coincides with the set of maximal edges of \( G' \). \( \square \)

The equivalence of Theorem \footnote{3} and Theorem \footnote{5} can now be seen as follows. Theorem \footnote{5} follows directly from Lemma \footnote{9} and Theorem \footnote{4}. We now show that Theorem \footnote{4} can be proven using Theorem \footnote{5}. Let \( G = (V, E) \) be a hypergraph, and let \( w \) be the treewidth of its intersection graph. From Lemma \footnote{10} it follows that \( G \) is a partial hypergraph of an \( \alpha \)-acyclic hypergraph \( G' \) of rank \( w + 1 \). By Theorem \footnote{5} there exists an extended formulation of \( MP_{G'} \) with \( O(2^w|V|) \) variables and constraints. Since each edge of \( G \) is also an edge of \( G' \), this is also an extended formulation of \( MP_G \).

Let us now compare the strengths of Theorem \footnote{2} and Theorem \footnote{5}. We demonstrate that neither of these results implies the other one by showing that neither of the two classes of kite-free \( \beta \)-acyclic hypergraphs and constant-treewidth \( \alpha \)-acyclic hypergraphs contains the other class. First, consider the hypergraph \( G_1 = (V, E) \), where \( V = \{v_1, \ldots, v_{2m+1}\} \), for some integer \( m \geq 1 \), and where \( E \)
contains all subsets of \( \{v_i, v_{i+1}, v_{i+2}\} \) for every odd \( i \in \{1, \ldots, 2m-1\} \). It is simple to check that \( G_1 \) is an \( \alpha \)-acyclic hypergraph with rank \( r = 3 \), while it contains many \( \beta \)-cycles. Hence, \( G_1 \) satisfies the assumptions of Theorem \([5]\) but does not satisfy the assumptions of Theorem \([2]\). Now consider a laminar hypergraph \( G_2 \) with an edge containing all of its nodes. As we detailed in Section \([3.3.3]\), \( G_2 \) is \( \gamma \)-acyclic and hence is kite-free \( \beta \)-acyclic and therefore a compact extended formulation for its multilinear polytope is given by Theorem \([2]\). However, the rank of \( G_2 \) is equal to \( n \) and hence is not a constant, implying that this hypergraph does not satisfy the assumptions of Theorem \([5]\).

5 Technical proofs

In this section we provide the proofs omitted in Section \([3]\).

5.1 Proof of Proposition \([6]\)

Let \( G = (V, E) \) be a 2-laminar \( \beta \)-acyclic hypergraph. We prove the theorem by induction on the number of nodes of \( G \). In the base case, \( G \) consists of a single node \( v \). In this case, system \([20]\) simplifies to \( 0 \leq z_v \leq 1 \), which is clearly the multilinear polytope. To perform the inductive step, we select a particular node \( \tilde{v} \in G \). To do so, we first define an extremal element.

For each \( e \in E \), define \( I(e) := \{p \in V \cup E : p \subseteq e, p \not\subset e' \}, \) for \( e' \in E, e' \subset e \) and \( U(e) := \{v \in V : \{v\} = e_1 \cap e_2, \) for some \( e_1, e_2 \in I(e) \cap E \}. \) Let \( \hat{e} \in E \) and consider a partial hypergraph of \( G \) denoted by \( H_\hat{e} \) with \( V(H_\hat{e}) = \hat{e} \) and \( E(H_\hat{e}) = I(\hat{e}) \cap E \). We refer to an element \( p \in I(\hat{e}) \) as an extremal element of \( H_\hat{e} \) if the set \( w_p = p \cap (\bigcup_{e \supseteq \hat{e}} U(e)) \) is either empty or consists of a single node and \( w_p \neq p \). If an extremal \( p \) is an edge, we refer to it as an extremal-edge. Since \( p \subseteq \hat{e} \), it follows that \( p \cap (\bigcup_{e \supseteq \hat{e}} U(e)) = p \cap (\hat{e} \cap (\bigcup_{e \supseteq \hat{e}} U(e))) = p \cap w_\hat{e} \). Hence, we have \( w_p = (p \cap w_\hat{e}) \cup (p \cap U(\hat{e})) \). The hypergraph \( H_\hat{e} \) is a partial hypergraph of the \( \beta \)-acyclic hypergraph \( G \). Hence by part (i) of Lemma \([1]\) and Lemma \([4]\), the set \( E(H_\hat{e}) \) has at least two leaves. From the definition of \( H_\hat{e} \) it follows that an edge \( \hat{e} \) is a leaf of \( E(H_\hat{e}) \) when the set \( N(\hat{e}) = \hat{e} \cap (\bigcup_{e \supseteq \hat{e}} E(H_\hat{e}) \backslash \{\hat{e}\}) = \hat{e} \cap U(\hat{e}) \) consists of at most one node. Since \( N(\hat{e}) \subseteq w_\hat{e} \), it follows that every extremal-edge of \( H_\hat{e} \) is a leaf of \( E(H_\hat{e}) \) but the converse is not true. In fact, \( H_\hat{e} \) may not have any extremal-edges in general. However, as we show next, in the special case where \( \hat{e} \) is already an extremal-edge, \( H_\hat{e} \) has an extremal-edge as well.

Claim 4. Let \( e_j \in I(e_i) \) and suppose that \( e_j \) is an extremal-edge of \( H_{e_i} \). If \( I(e_j) \cap E \neq \emptyset \), then \( H_{e_j} \) has an extremal-edge.

Proof of claim. We show that \( H_{e_j} \) has an extremal-edge \( e_k \). We have \( w_{e_k} = (e_k \cap w_{e_j}) \cup (e_k \cap U(e_j)) \). Since \( e_j \) is an extremal-edge of \( H_{e_i} \), the set \( w_{e_j} \) is either empty or consists of a single node. If \( H_{e_j} \) has a connected component consisting of a single edge \( e_k \), then \( e_k \) is an extremal-edge of \( H_{e_j} \) as \( e_k \cap U(e_j) = \emptyset \), implying \( w_{e_k} \subseteq w_{e_j} \). Hence, suppose that each connected component in \( H_{e_j} \) has at least two edges. By part (i) of Lemma \([1]\), the edge set of each connected component in \( H_{e_j} \) has at least two leaves \( e' \) and \( e'' \); that is, each of the two sets \( e' \cap U(e_j) \) and \( e'' \cap U(e_j) \) consist of a single node. Clearly, if (i) \( w_{e_j} \subseteq e' \) and \( w_{e_j} \subseteq e'' \) which implies \( w_{e_j} \subseteq U(e_j) \) or (ii) \( w_{e_j} \not\subseteq e' \) and \( w_{e_j} \not\subseteq e'' \), then we have \( w_{e'} = e' \cap U(e_j) \) and \( w_{e''} = e'' \cap U(e_j) \), implying both \( e' \) and \( e'' \) are extremal-edges of \( H_{e_j} \). Hence, the only remaining case is \( w_{e_j} \subseteq e' \) and \( w_{e_j} \not\subseteq e'' \) (resp. \( w_{e_j} \not\subseteq e' \) and \( w_{e_j} \subseteq e'' \)), in which case \( e'' \) (resp. \( e' \)) is an extremal-edge of \( H_{e_j} \). Hence, \( H_{e_j} \) has an extremal-edge.

We now describe the algorithm to select the node \( \tilde{v} \) for the inductive step. Without loss of generality, we assume that \( G \) has an edge containing all its nodes; i.e., \( e_0 := V \in E \), as otherwise
by Theorem 1 in [14], the multilinear set $S_G$ is decomposable into a collection multilinear subsets each of which corresponds to a 2-laminar $β$-acyclic hypergraph with an edge containing all of its nodes. First consider the edge $e_0$; if $I(e_0) = V$, we let $\tilde{v}$ be any node in $e_0$. Otherwise, by Claim 4, we select an extremal-edge of $H_{e_0}$ denoted by $e_1$. If $I(e_1) \subset V$, then we let $\tilde{v}$ be a node in $e_1 \setminus w_{e_1}$. Otherwise, we apply Claim 4 recursively, until we obtain an extremal-edge $e_t$ of $H_{e_{t-1}}$ with $I(e_t) \subset V$ and we let $\tilde{v} \in e_t \setminus w_{e_t}$. Note that $e_j \setminus w_{e_j} \neq \emptyset$ for all $j \in \{1, \ldots, t\}$, as for the extremal edge $e_j$, the set $w_{e_j}$ is either empty or consists of a single node. Denote by $\tilde{E}$ the set of all edges of $G$ containing the node $\tilde{v}$. By the above construction, the set $\tilde{E}$ consists of a sequence of nested edges $e_0 \supset e_1 \supset \ldots \supset e_t$, where each $e_i$, $i \in \{1, \ldots, t\}$ is an extremal-edge of $H_{e_{i-1}}$.

**The inductive step.** Denote by $G_0$ (resp. $G_1$) the hypergraph corresponding to the face of $\text{MP}_G$ with $z_{\tilde{v}} = 0$ (resp. $z_{\tilde{v}} = 1$). We have $\text{MP}_G = \text{conv}(\text{MP}_{G_0} \cup \text{MP}_{G_1})$. Clearly, both $G_0$ and $G_1$ are 2-laminar $β$-acyclic hypergraphs and $|V(G_0)| = |V(G_1)| = |V(G)| - 1$. Hence, $\text{MP}_{G_0}$ and $\text{MP}_{G_1}$ can be obtained from the induction hypothesis.

Then $\text{MP}_{G_0}$ is given by

\[
\begin{align*}
z_{\tilde{v}} &= 0 \\
z_v &\leq 1 \\
z_e &= 0 \\
-z_p &\leq 0 \\
-z_p + z_e &\leq 0 \\
\sum_{v \in U(e)} (1 - \delta_e(v))z_v + \sum_{p \in I(e)} z_p - z_e &\leq \omega(e) - 1 \\
&\forall v \in V \setminus \tilde{v} \\
&\forall e \in \tilde{E} \\
&\forall p \in V \cup E \setminus \tilde{E}, p \not\subset f, f \in E \setminus \tilde{E} \tag{23} \\
&\forall e \in E \setminus \tilde{E}, \forall p \in I(e) \\
&\forall e \in E \setminus \tilde{E}.
\end{align*}
\]

Moreover, $\text{MP}_{G_1}$ is given by

\[
\begin{align*}
z_{\tilde{v}} &= 1 \\
z_v &\leq 1 \\
z_e &= z_{e \setminus \{\tilde{v}\}} \\
-z_{e_0} &\leq 0 \\
-z_p + z_e &\leq 0 \\
\sum_{v \in U(e)} (1 - \delta_e(v))z_v + \sum_{p \in I(e)} z_p - z_e &\leq \omega(e) - 1 \\
&\forall v \in V \setminus \tilde{v} \\
&\forall e \in \tilde{E} : e \setminus \{\tilde{v}\} \in V \cup E \tag{24} \\
&\forall e \in E, \forall p \in I(e) \\
&\forall e \in E.
\end{align*}
\]

The last inequalities of systems (23) and (24) follow from the facts that for each $e \in E$, we have $\delta_e(v) = 0$ for all $v \in I(e)$ and $\delta_e(v) = 1$ for all $v \in e \setminus U(e) \cup I(e)$. Using Balas formulation for the union of polytopes [1], it follows that the polytope $\text{MP}_G$ is the projection onto the space of the
Projection orderings for specific order, and show that the projection is given by (20).

We now project out the variables \(z^0\), \(z^1\), \(\lambda_0\), \(\lambda_1\) from system (25) and obtain an explicit description for MP\(_G\). From (25), it follows that \(z^0_v = 0\), \(z^1_v = z_v\), \(\lambda_0 = 1 - z_v\), \(\lambda_1 = z_v\), \(z^0_v = z_v - z^1_v\) for all \(v \in V\setminus\{\tilde{v}\}\), \(z^1_v = z_e\), for all \(e \in \tilde{E}\), \(z^1_e = z_e\) for all \(e \in \tilde{E}\) such that \(e \setminus \{\tilde{v}\} \in V \cup E\), \(z^0_v = z_e - z^1_e\) for all \(e \in E \setminus \tilde{E}\). Hence, by projecting out \(\lambda_0\), \(\lambda_1\), \(z^0_p\) for all \(p \in V \cup E\) and \(z^1_p\) for all \(p \in \{\tilde{v}\} \cup \tilde{E}\), we obtain:

\[
\begin{align*}
    z_v - z^1_v &\leq 1 - z_v & \forall v \in V \setminus \tilde{v} \\
    (z_p - z^1_p) &\leq 0 & \forall p \in I(e), e \in \tilde{E} \\
    - (z_p - z^1_p) + (z_e - z^1_e) &\leq 0 & \forall e \in E \setminus \tilde{E}, \forall p \in I(e) \\
    \sum_{e \in U(e)} (1 - \delta_e(v)) (z_v - z^1_v) + \sum_{p \in I(e)} (z_p - z^1_p) - (z_e - z^1_e) &\leq (\omega(e) - 1)(1 - z_v) & \forall e \in E \setminus \tilde{E}
\end{align*}
\]

and

\[
\begin{align*}
    - z_{\bar{e}0} &\leq 0 & \forall v \in V \setminus \tilde{v} \\
    z^1_e &\leq z_{\bar{e}} \\
    -z^1_p + z^1_e &\leq 0 & \forall e \in E, \forall p \in I(e) \\
    \sum_{e \in U(e)} (1 - \delta_e(v)) z^1_v + \sum_{p \in I(e)} z^1_p - z^1_e &\leq (\omega(e) - 1)z_{\bar{e}} & \forall v \in V \setminus \tilde{v}
\end{align*}
\]

In the following, we project out \(z^1_v, v \in V \setminus \tilde{v}, z^1_e, e \in E \setminus \tilde{E}\) from systems (26) and (27) in a specific order, and show that the projection is given by (20).

**Projection orderings for \(I(e)\).** For any \(e \in E\), the elements of \(I(e)\) have the running intersection property. To see this, note that the set of edges in \(I(e)\) is a subset of the edge set of a \(\beta\)-acyclic hypergraph \(G\), and hence by Lemma 4 has the running intersection property. In addition, by construction, the nodes in \(I(e)\) are not contained in any edge in \(I(e)\). Now suppose that \(e\) is an extremal-edge of \(H_f\), where \(e \in I(f)\). Let \(p_s\) be an element of \(I(e)\) that contains \(w_e\). Clearly, if \(w_e = \emptyset\), then \(p_s\) can be any element of \(I(e)\). We define a projection ordering for \(I(e)\), denoted by \(\tilde{O}(e)\), as a running intersection ordering of \(I(e)\) in which \(p_s\) is the first element. By part (ii) of Lemma 4, such an ordering exists. We define the hypergraph \((V', E')\) obtained from \(H_e\) by removing some \(p \in I(e)\) as \(V' := V(H_e) \setminus \{v : v \in p\}\) and \(E' := E(H_e) \setminus \{p\}\). For any \(p \in I(e)\), we denote by \(H_{\tilde{O}(e)}\), the hypergraph obtained from \(H_e\) by removing all elements appearing after \(p\) in \(\tilde{O}(e)\). By definition of \(\tilde{O}(e)\) and the proof of Claim 4, we have:
Claim 5. Let $e$ be an extremal-edge of $H_f$, where $e \in I(f)$ and let $\bar{O}(e) = p_1, \ldots, p_r$, where $r = |I(e)|$, be a projection ordering for $I(e)$. Then $p_j$ is an extremal element of $H_{e^{\le p_j}}$ for all $j \in \{1, \ldots, r\}$.

Consider the projection ordering $\bar{O}(e)$ as defined in Claim 5. Define $U^{\le p_j}(e) := \{v \in V : \{v\} = e_1 \cap e_2, e_1, e_2 \in E(H_{e^{\le p_j}})\}$ and $\bar{w}_{p_j} := (p_j \cap w_e) \cup (p_j \cap U^{\le p_j}(e))$. By definition of a projection ordering $\bar{O}(e)$ we have

$$\bar{w}_{p_1} = w_e, \quad \bar{w}_{p_j} = N(p_j), \quad \forall 2 \le j \le r,$$

where the sets $N(p_j)$ are as defined in (3). Since $e$ is an extremal-edge of $H_f$ and $p_1, \ldots, p_r$ is a running intersection ordering of $I(e)$, it is simple to see that $\bar{w}_{p_j}$ is either empty or consist of a single node. In the remainder of the proof, given an edge $e \in E$, we use a projection ordering $\bar{O}(e) = p_1, \ldots, p_r$ to recursively project out variables $z_{p_j}, j \in \{1, \ldots, r\}$.

Projecting out $z_{p_j}$ corresponding to $G_e$ for some $e \in E \setminus \bar{E}$. Consider an edge $\bar{e} \in E \setminus \bar{E}$ and let $G_{\bar{e}}$ denote the section hypergraph of $G$ induced by $\bar{e}$. Note that for a 2-laminar hypergraph, the section hypergraph induced by an edge coincides with the subhypergraph induced by the same edge. Suppose that $\bar{e}$ is an extremal-edge of $H_f$, where $\bar{e} \in I(f)$. Our objective is to project out variables $z_{p_j}$ for all $v \in V(G_{\bar{e}}) \setminus w_{\bar{e}}$ and $z_{p_j}$ for all $e \in E(G_{\bar{e}}) \setminus \{\bar{e}\}$ from systems (26) and (27). To this end, we make use of the following result:

Claim 6. Let $e \in E \setminus \bar{E}$ and suppose that $e$ is an extremal-edge of $H_f$, where $e \in I(f)$. Let $\bar{O}(e)$ be a projection ordering for $I(e)$ with the corresponding sets $\bar{w}_p, p \in I(e)$ as defined by (28). Consider the following inequalities:

\[
\begin{align*}
\{ & \quad z_{p_j}^1 \leq z_{\bar{e}} \quad \text{if } \bar{w}_p = \emptyset, \text{ or } p = w_e, \forall p \in I(e) \\
& \quad z_{p_j}^1 \leq z_{v_{p_j}}^1, \quad z_{v_{p_j}}^1 \leq z_{\bar{e}} \quad \text{if } \bar{w}_p = \{v_{p_j}\}, \forall p \in I(e) \\
& \quad z_{e}^1 \leq z_{p_j}^1 \quad \forall p \in I(e) \\
& \quad \sum_{v \in U(e)} (1 - \delta_e(v))z_{v}^1 + \sum_{p \in I(e)} z_{p_j}^1 - z_{e}^1 \leq (\omega(e) - 1)z_{\bar{e}}
\end{align*}
\]  

\[
\begin{align*}
\{ & \quad z_{p_j}^1 - z_{p_j}^1 \leq 1 - z_{\bar{e}} \quad \text{if } \bar{w}_p = \emptyset, \text{ or } p = w_e, \forall p \in I(e) \\
& \quad z_{p_j}^1 - z_{p_j}^1 \leq z_{v_{p_j}}^1 - z_{v_{p_j}}^1, \quad z_{v_{p_j}}^1 - z_{v_{p_j}}^1 \leq 1 - z_{\bar{e}} \quad \text{if } \bar{w}_p = \{v_{p_j}\}, \forall p \in I(e) \\
& \quad z_{e}^1 - z_{e}^1 \leq z_{p_j}^1 \quad \forall p \in I(e) \\
& \quad \sum_{v \in U(e)} (1 - \delta_e(v))z_{v}^1 + \sum_{p \in I(e)} z_{p_j}^1 - z_{e}^1 \leq (\omega(e) - 1)(1 - z_{\bar{e}})
\end{align*}
\]

Then by projecting out $z_{p_j}^1$ for all $p \in I(e) \cup U(e) \setminus w_e$, we obtain

\[
\begin{align*}
z_{p_j}^1 & \leq 1 \quad \forall p \in U(e) \text{ and } \forall p \in I(e) \text{ s.t. } \bar{w}_p = \emptyset \\
z_{p_j}^1 & \leq z_{v_{p_j}}^1 \quad \forall p \in I(e) \text{ s.t. } \bar{w}_p = \{v_{p_j}\} \\
z_{e}^1 & \leq z_{p_j}^1 \quad \forall p \in I(e) \\
\sum_{v \in U(e)} (1 - \delta_e(v))z_{v} + \sum_{p \in I(e)} z_{p_j} - z_{e} & \leq \omega(e) - 1
\end{align*}
\]

\[\text{together with}\]

\[
\begin{align*}
z_{e}^1 & \leq z_{\bar{e}} \\
z_{e}^1 & \leq 1 - z_{\bar{e}},
\end{align*}
\]

26
Finally, the inequalities obtained by projecting out \( z\) are:

\[
\begin{align*}
  z^1_e &\leq z^1_{v_e} \\
  z_e - z^1_e &\leq z_{v_e} - z^1_{v_e} \\
  z^1_{v_e} &\leq z_{\bar{v}} \\
  z_{v_e} - z^1_{v_e} &\leq 1 - z_{\bar{v}},
\end{align*}
\] (37)

if \( w_e = \emptyset \), and

if \( w_e = \{v_e\} \).

**Proof of claim.** First suppose that \( w_e = \emptyset \). Let \( \bar{p} \) be the last element of \( \bar{O}(e) \). We project out the variable \( z^1_p \) from inequalities (29) using Fourier–Motzkin elimination. From (29) and (30) we obtain

\[
\begin{align*}
  \{ & z_{\bar{p}} \leq 1 & \text{if } \bar{w}_p = \emptyset \\
  & z_{\bar{p}} \leq z_{v_p} & \text{if } \bar{w}_p = \{v_p\},
\end{align*}
\] (38)

while from (30) and (33) we obtain

\[ z_e \leq z_{\bar{p}}. \] (39)

From (31) and (34) we obtain

\[ \sum_{v \in U(e)} (1 - \delta_e(v)) z_v + \sum_{p \in I(e)} z_p - z_e \leq \omega(e) - 1. \] (40)

From (30) and (31) we obtain

\[ \sum_{v \in U(e)} (1 - \delta_e(v)) z^1_v + \sum_{p \in I(e) \setminus \{\bar{p}\}} z^1_p \leq (\omega(e) - 1)z_{\bar{v}}. \] (41)

We claim that inequality (41) is redundant. To see this, consider a running intersection ordering \( O \) of \( I(e) \) in which \( \bar{p} \) is the first element. Note that by part (ii) of Lemma 4 such an ordering exists. Let the sets \( N(p), p \in I(e) \) be defined by (3). Now for each \( p \in O \setminus \{\bar{p}\} \), consider the following inequalities all of which are either present in system (27) or are implied by it: \( z^1_p \leq z_{\bar{v}} \) if \( N(p) = \emptyset \), and \( z^1_p \leq z^1_{v_p} \) if \( N(p) = \{v_p\} \). By summing up these inequalities for all \( p \in O \setminus \{\bar{p}\} \), we obtain (41). By symmetry, projecting out \( z^1_p \) from (33) and (34) yields a redundant inequality. By projecting out \( z^1_p \) from (29) and (30) we obtain

\[ z^1_e \leq z_{\bar{v}}, \] (42)

if \( \bar{w}_p = \emptyset \), and \( z^1_e \leq z^1_{v_p} \) if \( \bar{w}_p = \{v_p\} \). The latter inequality is redundant as it is implied by inequalities (29), for some \( p \neq \bar{p} \) such that \( p \supset v_p \). By symmetry, from (32) and (33) we obtain

\[ z_e - z^1_e \leq 1 - z_{\bar{v}} \] (43)

if \( \bar{w}_p = \emptyset \), and we obtain a redundant inequality if \( \bar{w}_p = \{v_p\} \). From (31) and (32) we obtain

\[
\begin{cases}
  \sum_{v \in U(e)} (1 - \delta_e(v)) z^1_v + z_p + \sum_{p \in I(e) \setminus \{\bar{p}\}} z^1_p - z^1_e \leq (\omega(e) - 2)z_{\bar{v}} + 1 & \text{if } \bar{w}_p = \emptyset \\
  (2 - \delta_e(v_p)) z^1_{v_p} - z_{v_p} + \sum_{v \in U(e) \setminus \{v_p\}} (1 - \delta_e(v)) z^1_v + z_p + \sum_{p \in I(e) \setminus \{\bar{p}\}} z^1_p - z^1_e \leq (\omega(e) - 1)z_{\bar{v}} & \text{if } \bar{w}_p = \{v_p\}
\end{cases}
\] (44)

Finally, the inequalities obtained by projecting out \( z^1_p \) from (29) and (34) are given by

\[
\begin{cases}
  \sum_{v \in U(e)} (1 - \delta_e(v)) (z_v - z^1_v) + z_p + \sum_{p \in I(e) \setminus \{\bar{p}\}} (z_p - z^1_p) - (z_e - z^1_e) \leq (\omega(e) - 2)(1 - z_{\bar{v}}) + 1 & \text{if } \bar{w}_p = \emptyset \\
  (2 - \delta_e(v_p)) (z_{v_p} - z^1_{v_p}) - z_{v_p} + \sum_{v \in U(e) \setminus \{v_p\}} (1 - \delta_e(v)) (z_v - z^1_v) + z_p + \sum_{p \in I(e) \setminus \{\bar{p}\}} (z_p - z^1_p) - (z_e - z^1_e) \leq (\omega(e) - 1)(1 - z_{\bar{v}}) & \text{if } \bar{w}_p = \{v_p\}
\end{cases}
\] (45)
Hence, projecting out $z^1_p$ from inequalities (29)-(31), yields inequalities (32), (33), (34), (35), and (36). Denote by $\tilde{p}$ the element before $p$ in $\mathcal{O}(e)$. Clearly, among the inequalities obtained as a result of the above projection, the only ones containing $z^1_{\tilde{p}}$ are inequalities (34) and (35).

Hence, to project out $z^1_p$ from the system (29)-(34), it suffices to consider inequalities (34) and (35) together with inequalities (29), (30), (32), and (33), for $p = \tilde{p}$. Using a similar line of arguments as above, it follows that the only non-redundant inequalities obtained from this projection are of the form (38) and (39) with $\tilde{p}$ replaced by $p$ together with those obtained by projecting out $z^1_{\tilde{p}}$ from inequalities (32) (resp. (29)) and (44) (resp. (45)).

We now apply this approach recursively to project out $z^1_p$ for all elements $p \in \mathcal{O}(e)$ in reverse order. From (44) and (45) it follows that for a node $\tilde{v} \in U(e)$, after projecting out $z^1_p$ corresponding to the $\delta_p(v) - 1$ edges with $\tilde{w}_p = \{\tilde{v}\}$, the coefficient of $z^1_0$ in these inequalities becomes zero. Moreover, at this point, the only inequalities containing $z^1_0$ are $z^1_0 \leq z_0$ and $z_0 - z^1_0 \leq 1 - z_0$. Hence, projecting out $z^1_0$ yields $z_0 \leq 1$. As the number of elements $p$ in $\mathcal{O}(e)$ with $\tilde{w}_p = \emptyset$ is equal to $\omega(e)$, after projecting out $z^1_p$ for all $p \in \mathcal{O}(e)$ from inequalities (32) and (44) we obtain $\sum_{v \in U(e)} (1 - \delta_p(v))z_v + \sum_{p \in I(e)} z_p - z^1_p \leq -z_0 + \omega(e)$. However, this inequality is implied by inequalities (30) and (43). By symmetry, we conclude that the inequality obtained from the recursive projection of $z^1_p$, $p \in \mathcal{O}(e)$ from (29) and (45) is redundant. Hence, by projecting out $z^1_p$, for all $p \in I(e) \cup U(e)$ from inequalities (29)-(44), we obtain inequalities (35) and (36).

Next, suppose that $w_e = \{v_e\}$ for some $v_e \in V$. Denote by $p_s$ the first element in $\mathcal{O}(e)$. Recall that by definition of $\mathcal{O}(e)$, we have $w_e = v_e$ if $v_e \in I(e)$ and $p_s = \bar{e}$ where $\bar{e} \supset v_e$ is an edge in $I(e)$, otherwise. We employ the recursive projection as detailed above to project out $z^1_p$ for all $p \in U(e) \cup I(e) \setminus \{p_s\}$. Then follows that projecting out $z^1_p$ for all $p \in U(e) \cup I(e) \setminus \{p_s\}$ yields $\sum_{v \in U(e)} (1 - \delta_p(v))z_v + \sum_{p \in I(e) \setminus \{p_s\}} z_p + z^1_p - z^1_{p_s} \leq \omega(e) - 1$. This inequality is implied by inequality (33) for $p = p_s$ and inequality (40). Symmetrically, we conclude that the inequality obtained by projecting out $z^1_p$ for all $p \in U(e) \cup I(e) \setminus \{p_s\}$ from inequalities (29) and (44) is redundant. Finally, if $p_s = \bar{e}$, we project out $z^1_{p_s}$, which is only present in inequalities (29), (30), (32), (33) with $p = \bar{e}$ and $w_p = \{v_e\}$, implying its projection yields inequalities (37). Hence, we have shown that the final projection is given by inequalities (35) and (36).

Recall that our objective is to project out $z^1_v$ for all $v \in V(G_{\bar{e}}) \setminus w_{\bar{e}}$ and $z^1_{e}$ for all $e \in E(G_{\bar{e}}) \setminus \{\bar{e}\}$ from systems (26) and (27), where $G_{\bar{e}}$ is the section hypergraph of $G$ induced by $\bar{e}$ and $\bar{e} \in E \setminus \bar{E}$ is an extremal-edge of $H_f$ and $\bar{e} \in I(f)$. More precisely, we consider the following inequalities:

$$z_v - z^1_v \leq 1 - z_0 \quad \forall v \in \bar{e}$$
$$-(z_p - z^1_p) + (z_e - z^1_e) \leq 0 \quad \forall e \in E(G_{\bar{e}}), \forall p \in I(e)$$
$$\sum_{v \in U(e)} (1 - \delta(v))z_v + \sum_{p \in I(e)} (z_p - z^1_p) - (z_e - z^1_e) \leq (\omega(e) - 1)(1 - z_0) \quad \forall e \in E(G_{\bar{e}}),$$

and

$$z^1_v \leq z_0 \quad \forall v \in \bar{e}$$
$$-z^1_p + z^1_e \leq 0 \quad \forall e \in E(G_{\bar{e}}), \forall p \in I(e)$$
$$\sum_{v \in U(e)} (1 - \delta(v))z_v + \sum_{p \in I(e)} z^1_p - z^1_e \leq (\omega(e) - 1)z_0 \quad \forall e \in E(G_{\bar{e}}).$$

Claim 7. Consider the section hypergraph $G_{\bar{e}}$ as defined above. By projecting out $z^1_v$, $v \in V(G_{\bar{e}}) \setminus w_{\bar{e}}$ and $z^1_{e}, e \in E(G_{\bar{e}}) \setminus \{\bar{e}\}$ from inequalities (46) and (47), we obtain

$$z_v \leq 1 \quad \forall v \in \bar{e}$$
$$-z_p + z_e \leq 0 \quad \forall e \in E(G_{\bar{e}}), \forall p \in I(e)$$
$$\sum_{v \in U(e)} (1 - \delta(v))z_v + \sum_{p \in I(e)} z_p - z_e \leq \omega(e) - 1 \quad \forall e \in E(G_{\bar{e}}).$$
together with

\[z^1_e \leq z_\bar{e} \]
\[z_\bar{e} - z^1_e \leq 1 - z_0,\]  \hspace{1cm} (49)

if \(w_\bar{e} = \emptyset\) and

\[z^1_e \leq z^1_v \]
\[z_\bar{e} - z^1_e \leq z_{v_\bar{e}} - z^1_{v_\bar{e}} \]
\[z^1_{v_\bar{e}} \leq z_0 \]
\[z_{v_\bar{e}} - z^1_{v_\bar{e}} \leq 1 - z_0,\]  \hspace{1cm} (50)

if \(w_\bar{e} = \{v_\bar{e}\}\).

Proof of claim. The proof is by induction on the number of edges of \(G_\bar{e}\). In the base case, we have \(|E(G_\bar{e})| = 1\), implying \(I(e) \subset V\) and \(U(e) = \emptyset\). In this case, inequalities (46) and (47) coincide with inequalities \((29)-(31)\) of Claim 6 by letting \(e = \bar{e}\), in which case we have \(\bar{w}_p = \emptyset\) for all \(p \in \bar{O}(e) \setminus w_\bar{e}\). Hence, by projecting out \(z^1_p\) for all \(p \in \bar{I}(\bar{e}) \setminus w_\bar{e}\), we obtain inequalities (35) and (36) (resp. (35) and (37)) which coincide with inequalities (48) and (49) (resp. (48) and (50)) for \(w_\bar{e} = \emptyset\) (resp. \(w_\bar{e} = \{v_\bar{e}\}\)).

Suppose that \(|E(G_\bar{e})| \geq 2\). Since \(\bar{e}\) is an extremal-edge of \(H_f\), where \(\bar{e} \in I(f)\), we can construct a projection ordering \(\bar{O}(\bar{e})\) of \(I(\bar{e})\) with the corresponding sets \(\bar{w}_p\) defined by (28). Define \(\bar{O}(\bar{e}) = \bar{O}(\bar{e}) \setminus V(G_\bar{e})\) and let \(r := |\bar{O}(\bar{e})|\). Denote by \(p_r\) the last element in \(\bar{O}(\bar{e})\) and let \(G_{p_r}\) denote the section hypergraph of \(G_\bar{e}\) induced by \(p_r\). Clearly, \(G_{p_r}\) has at least one fewer edge than \(G_\bar{e}\) and by construction \(p_r\) is an extremal-edge of \(H_\bar{e}\). Hence, by the induction hypothesis, by projecting out \(z^1_v\) for all \(v \in V(G_{p_r}) \setminus \bar{w}_{p_r}\) and \(z^1_\bar{e}\) for all \(e \in E(G_{p_r}) \setminus \{p_r\}\) from inequalities (46) and (47), we obtain the system defined in the statement of the claim with \(\bar{e}\) replaced by \(p_r\). Similarly, we consider in reverse order, each element \(p_j \in \bar{O}(\bar{e})\) and since by Claim 3 \(p_j\) is an extremal-edge of \(H^{\leq p_j}_\bar{e}\), we can use the induction hypothesis to project out \(z^1_v\), \(v \in V(G_{p_j}) \setminus \bar{w}_{p_j}\) and \(z^1_\bar{e}\), \(e \in E(G_{p_j}) \setminus \{p_j\}\) from inequalities (46) and (47). It then follows that the remaining inequalities containing \(z^1_p\), \(p \in I(\bar{e}) \cup U(\bar{e})\) are identical to inequalities (29)-(31) defined in Claim 6 with \(e = \bar{e}\); hence the final projection can be obtained accordingly and this completes the proof.

Projecting out \(z^1_p\) corresponding to \(G_e\) for some \(e \in E\). Let \(e \in E\) and denote by \(\bar{p}\) the element of \(I(e)\) containing the node \(v\). Consider a projection ordering \(\bar{O}(e)\) of \(I(e)\) in which \(\bar{p}\) is the first element and as before, let the sets \(\bar{w}_{p}, p \in \bar{O}(e)\) be given by (28). Clearly, \(z^1_e = z_\bar{e}\) and \(z^1_{\bar{p}} = z_{\bar{p}}\). Consider the following inequalities:

\[-z_{\bar{p}} + z^1_{\bar{p}} \leq 0 \quad \forall p \in I(e) \setminus \{\bar{p}\}\]
\[\left\{ \begin{array}{l}
z_{\bar{p}} - z^1_{\bar{p}} \leq 1 - z_\bar{e} \\
z_{\bar{p}} - z^1_{\bar{p}} \leq z_{v_\bar{p}} - z^1_{v_\bar{p}} , \ z_{v_\bar{p}} - z^1_{v_\bar{p}} \leq 1 - z_\bar{e} \\
z_e \leq z^1_p \quad \forall p \in I(e) \setminus \{\bar{p}\}\end{array} \right. \quad \text{if } \bar{w}_p = \emptyset, \ \forall p \in I(e) \setminus \{\bar{p}\}\]
\[\left\{ \begin{array}{l}
z^1_{\bar{p}} \leq z_\bar{e} \\
z^1_{\bar{p}} \leq z^1_{v_\bar{p}} , \ z^1_{v_\bar{p}} \leq z_\bar{e} \\
z_e \leq z^1_p \quad \forall p \in I(e) \setminus \{\bar{p}\}\end{array} \right. \quad \text{if } \bar{w}_p = \emptyset, \ \forall p \in I(e) \setminus \{\bar{p}\}\]
\[\sum_{v \in U(e)} (1 - \delta_e(v))z^1_v + \sum_{p \in I(e) \setminus \{\bar{p}\}} z^1_p + z_{\bar{p}} - z_e \leq (\omega(e) - 1)z_\bar{e}.\]  \hspace{1cm} (51)

We make use of the following claim to complete the proof of this theorem; we state this result without a proof as the proof as is similar to the proof of Claim 6.  

29
Claim 8. By projecting out $z_p^1$ for all $p \in I(e) \cup U(e)$ from system (51), we obtain

$$\begin{cases}
  z_p \leq 1 & \text{if } \bar{w}_p = \emptyset, \forall p \in I(e) \\
  z_p \leq z_{vp} & \text{if } \bar{w}_p = \{v_p\}, \forall p \in I(e) \\
  z_e \leq z_p & \forall p \in I(e) \\
  \sum_{v \in U(e)} (1 - \delta_e(v))z_v + \sum_{p \in I(e)} z_p - z_e \leq \omega(e) - 1.
\end{cases}$$ (52)

Characterization of $MP_G$. We now employ the results of Claims 7 and 8 to characterize $MP_G$ in the original space. Denote by $\bar{E}(G)$ the set containing the sequence of nested edges of $G$ containing $\bar{v}$. The proof is by induction on the cardinality of $\bar{E}(G)$. In the base case, we have $\bar{E}(G) = \{e_0\}$. By definition of $\bar{v}$, this implies that $E(G) = \{e_0\}$. Consider the system of inequalities defined by (51). By letting $e = e_0$, $\bar{v} = \bar{v}$, and $I(e_0) = V(G)$ which implies $\bar{w}_p = \emptyset$ for all $p \in I(e_0)$, these inequalities coincide with systems (26) and (27). Therefore, by Claim 8, in this case $MP_G$ is given by system (52), which coincides with system (20) with $I(e_0) = V$.

Now, suppose that $|\bar{E}(G)| \geq 2$ and define $\hat{e} := I(e_0) \cap \bar{E}(G)$. Consider a running intersection ordering $O(e_0)$ of the edges in $I(e_0)$ in which $\hat{e}$ is the first element. The existence of such an ordering follows from Lemmata 1 and 3. Denote by $w_e$ the intersection of each edge with all previous ones in $O(e_0)$. Let $\hat{e}$ be the last element in $O(e_0)$ and denote by $G_\hat{e}$ the section hypergraph of $G$ induced by $\hat{e}$. Clearly, $\hat{e} \notin \bar{E}(G)$ and $\hat{e}$ is an extremal-edge of $H_{e_0}$. Hence, by Claim 7 by projecting out $z_0^1$ for all $v \in V(G_\hat{e}) \setminus w_\hat{e}$ and $z_e^1$ for all $e \in E(G_\hat{e}) \setminus \{\hat{e}\}$ from inequalities containing these variables, we obtain system (53) together with inequalities (49) if $w_\hat{e} = \emptyset$, and inequalities (50) if $w_\hat{e} = \{v_\hat{e}\}$. Similarly, apply this projection recursively for each element $\hat{e}$ in $O(e_0) \setminus \{\hat{e}\}$ in a reverse order to project out $z_0^1$ for all $v \in V(G_\hat{e}) \setminus w_\hat{e}$ and $z_e^1$ for all $e \in E(G_\hat{e}) \setminus \{\hat{e}\}$, where $G_{\hat{e}}$ denotes the section hypergraph of $G$ induced by $\hat{e}$.

Let $G'$ denote the section hypergraph of $G$ induced by $\hat{e}$. Clearly, $G'$ is a 2-laminar $\beta$-acyclic hypergraph with $|\bar{E}(G')| = |\bar{E}(G)| - 1$. In addition, $w_\hat{e} = \emptyset$ as by construction, $\hat{e}$ is first element of $O(e_0)$. Hence, by the induction hypothesis, projecting out $z_p^1$ for all $p \in V(G') \cup E(G')$ gives system (20) with $G$ replaced by $G'$. It can now be seen that the remaining inequalities containing variables $z_p^1$, $p \in I(e_0) \cup U(e_0) \setminus \{\hat{e}\}$ coincide with system (51) by letting $e = e_0$ and $\bar{p} = \hat{e}$. Consequently, by projecting out these variables using Claim 8 we conclude that $MP_G$ is given by (20).

5.2 Proof of Theorem 1

In this proof we often consider $\beta$-cycles. It can be checked that a sequence $C = v_1, e_1, v_2, e_2, \ldots, v_t, e_t, v_{t+1} = v_1$ is a $\beta$-cycle in $G$ if and only if $t \geq 3$ and the edge $e_i$ contains $v_i, v_{i+1}$ and no other $v_j$, for $i = 1, \ldots, t$.

If $\bar{p} = \emptyset$, the result is obvious; thus, we assume that $\bar{p}$ is nonempty. Similarly, we assume that the sets $V(G) \setminus V(G_\omega)$ and $V(G) \setminus V(G_\alpha)$ are nonempty.

To proceed with the proof, we need a structural result regarding the hypergraph $\bar{G}_\alpha = (V_\alpha, \bar{E}_\alpha)$ obtained from $G_\alpha = (V_\alpha, E_\alpha)$ by removing edge $\bar{p}$, all the edges that strictly contain $\bar{p}$, and all the edges strictly contained in $\bar{p}$. Since $G_\alpha$ is 2-laminar, every edge in $\bar{E}_\alpha$ contains at most one node of $\bar{p}$. Let $w_1, \ldots, w_k$ be the nodes in $\bar{p}$. For each $i \in \{1, \ldots, p\}$, let $U_i$ contain node $w_i$ and the nodes $w \in V_\alpha$ for which there exists a chain in $\bar{G}_\alpha$ from $w_i$ to $w$.

Claim 9. The sets $U_1, \ldots, U_k$ are pairwise disjoint.
Note that, for every node \( w_i \) belongs to a set \( U_j \), for distinct indices \( i, j \) in \( \{1, \ldots, k\} \). By contradiction, assume that there exists a chain \( P \) in \( \tilde{G}_\alpha \) from \( w_i \) to \( w_j \). Without loss of generality, choose \( i, j, \) and \( P \) such that the length of \( P \) is minimal. We now show that \( C = P, \tilde{p}, w_i \) is a \( \beta \)-cycle in \( G_\alpha \). Since every edge in \( \tilde{E}_\alpha \) contains at most one node of \( \tilde{p} \), the chain \( P \) must have length at least two. By the minimality assumption \( \tilde{p} \) contains only the first \( (w_i) \) and last \( (w_j) \) nodes of \( P \). Again by minimality, each edge of \( P \) contains only the preceding and succeeding node of \( P \). Hence \( C = P, \tilde{p}, w_i \) is a \( \beta \)-cycle in \( G_\alpha \), which is a contradiction.

Consider now a node \( w \in V_\alpha \) that is not in \( \tilde{p} \). We show that \( w \) cannot belong to \( U_i \cap U_j \), for distinct indices \( i, j \) in \( \{1, \ldots, k\} \). By contradiction, assume that \( w \in U_i \cap U_j \). Then there exists a chain \( P^i \) in \( \tilde{G}_\alpha \) from \( w \) to \( w_i \) and a chain \( P^j \) in \( \tilde{G}_\alpha \) from \( w \) to \( w_j \). Without loss of generality, choose \( w, i, j, P^i, \) and \( P^j \) such that the sum of the lengths of \( P^i \) and \( P^j \) is minimal. We now show that \( C = P^i, \tilde{p}, P^j \) is a \( \beta \)-cycle in \( G_\alpha \). Note that all nodes of \( P^i \) (resp. \( P^j \)) except for \( w_i \) (resp. \( w_j \)) are not in \( \tilde{p} \), as otherwise such node \( w_i \in \tilde{p} \) would be in \( U_i \cap U_j \) (resp. \( U_i \cap U_j \)). By the minimality assumption, each edge of \( P^i \) contains only the preceding and succeeding node of \( P^i \). Symmetrically, each edge of \( P^j \) contains only the preceding and succeeding node of \( P^j \). Again by minimality, no edge of \( P^i \) (resp. \( P^j \)) contains nodes of \( P^j \) (resp. \( P^i \)) different from \( w \). Hence \( C = P^i, \tilde{p}, P^j \) is a \( \beta \)-cycle in \( G_\alpha \), which is a contradiction.

To simplify the notation in the remainder of the proof, it will be useful to consider the nodes in \( V_\alpha \setminus (\cup_{i=1}^k U_i) \) together with one of the sets \( U_1, \ldots, U_k \), instead than on their own. For this reason we define the sets \( W_i := U_i \), for \( i = 1, \ldots, k-1 \), and \( W_k := W_k \cup (V_\alpha \setminus (\cup_{i=1}^k U_i)) \).

Claim 10. The sets \( W_1, \ldots, W_k \) form a partition of \( V_\alpha \). Moreover, every edge of \( \tilde{G}_\alpha \) is contained in exactly one of these sets.

Proof of claim. Claim 9 directly implies that the sets \( W_1, \ldots, W_k \) form a partition of \( V_\alpha \). By definition of the sets \( U_1, \ldots, U_k \), every edge of \( \tilde{G}_\alpha \) is either contained in one of these set, or it is contained in \( V_\alpha \setminus (\cup_{i=1}^k U_i) \). Hence, every edge of \( \tilde{G}_\alpha \) is contained in exactly one of the sets \( W_1, \ldots, W_k \).

In the next two claims we utilize Claim 11 to obtain vectors in \( S_G \) by combining a number of vectors in \( S_{G_\alpha} \) and \( S_{G_\omega} \). We now explain how we write a vector \( z \) in the space defined by \( G \) in the rest of the proof by partitioning its components in a number of subvectors. The vector \( z_\cap \) contains the components of \( z \) corresponding to nodes and edges that are both in \( G_\alpha \) and in \( G_\omega \) (i.e., the nodes \( w_1, \ldots, w_k \), the edge \( \tilde{p} \) and any other edge contained in \( \tilde{p} \)). The vector \( z_\circ \) contains the components of \( z \) corresponding to edges that are in \( G_\alpha \) and strictly contain edge \( \tilde{p} \). For \( i = 1, \ldots, k \), the vector \( z_i \) contains the components of \( z \) corresponding to nodes in \( W_i \setminus \{w_i\} \) and edges contained in \( W_i \). Finally, the vector \( z_{k+1} \) contains the components of \( z \) corresponding to nodes and edges in \( G_\omega \) but not in \( G_\alpha \). Using these definitions, we can now write, up to reordering variables, \( z = (z_\cap, z_\circ, z_1, \ldots, z_k, z_\gamma, z_{k+1}) \). Similarly, we can write a vector \( z \) in the space defined by \( G_\alpha \) as \( z = (z_\cap, z_\circ, z_0, z_\gamma, z_k, z_{k+1}) \), and a vector \( z \) in the space defined by \( G_\omega \) as \( z = (z_\cap, z_\circ, z_0, z_\gamma, z_k, z_{k+1}) \).

Claim 11. Let \( z^\alpha = (z^\alpha_0, z^\alpha_1, \ldots, z^\alpha_k, z^\alpha_\gamma) \) be a vector in \( S_{G_\alpha} \), and let \( z^\omega = (z^\omega_0, z^\omega_1, \ldots, z^\omega_k, z^\omega_\gamma) \) be a vector in \( S_{G_\omega} \) such that \( z^\alpha_0 = z^\omega_0 = 1 \). Then the vector \( \tilde{z} = (z_\cap, z_\circ, z^\alpha, z^\omega, z_0, z_\gamma, z_{k+1}) \) is in \( S_G \).

Proof of claim. To prove the claim, we show that for each edge \( e \) of \( G \), we have \( \tilde{z}_e = \prod_{v,e} \tilde{z}_v \). First, we consider the edges of \( G_\omega \). For each edge \( e \) of \( G_\omega \), we have \( \tilde{z}_e = z^\omega_e = \prod_{v,e} z^\omega_v = \prod_{v,e} \tilde{z}_v \). Next, we consider the edges of \( G_\alpha \). For each edge \( e \) of \( G_\alpha \), we have \( \tilde{z}_e = z_\cap_e = z^\alpha_e = \prod_{v,e} z^\alpha_v = \prod_{v,e} \tilde{z}_v \). Note that, for every node \( v \in \tilde{p} \), we have \( z^\alpha_v = z^\omega_v = 1 \) since \( z^\alpha_0 = z^\omega_0 = 1 \). Hence we have \( \tilde{z}_e = \prod_{v,e} \tilde{z}_v \cdot \prod_{v,e} \tilde{z}_v = \prod_{v,e} \tilde{z}_v \).
Claim 12. Let $z^\alpha_1 = (z^\alpha_0, z^\alpha_1, \ldots, z^\alpha_k, z^\alpha_{\bar{k}+1})$, ..., $z^\alpha_k = (z^\alpha_0, z^\alpha_1, \ldots, z^\alpha_k, z^\alpha_{\bar{k}+1})$ be $k$ vectors in $S_{G_\alpha}$, and let $z^\omega = (z^\omega_0, z^\omega_1, \ldots, z^\omega_{k+1})$ be a vector in $S_{G_\omega}$ such that (1) $z^\alpha_0 = \cdots = z^\omega_0 = \bar{z}^\omega_p = 0$, (2) $z^\omega_{\bar{k}+1} = z^\omega_{\bar{k}+1}$ for every $i = 1, \ldots, k$. Then the vector $\hat{z} = (z^\alpha_0, z^\alpha_1, z^\alpha_2, \ldots, z^\alpha_k, z^\alpha_{\bar{k}+1})$ is in $S_G$.

Proof of claim. To prove the claim, we show that for each edge $e$ of $G$, we have $\hat{z}_e = \prod_{v \in e} \hat{z}_v$.

First, we consider the edges of $G_\omega$. For each edge $e$ in $G_\omega$, we have $\hat{z}_e = z^\omega_e = \prod_{v \in e} z^\omega_v = \prod_{v \in e} \hat{z}_v$.

Next, we consider the edges of $G_\alpha$. Note that we have $z^\alpha_0 = \cdots = z^\omega_0 = 0$ since $\bar{z}^\omega_p = 0 = \cdots = z^\alpha_p = z^\omega_p = 0$. For each edge $e$ contained in $\bar{p}$, we have $\hat{z}_e = z^\omega_e = \prod_{v \in e} z^\omega_v = \prod_{v \in e} \hat{z}_v$. For each edge $e$ that strictly contains $\bar{p}$, we have $z^\alpha_e = z^\omega_e = 0$ since $z^\alpha_0 = 0$; moreover $\prod_{v \in e} z^\omega_v = \prod_{v \in e} \hat{z}_v = \prod_{v \in e} z^\omega_v = \prod_{v \in e} \hat{z}_v = 0$. Finally, let $e$ be an edge that contains at most one node of $\bar{p}$.

We have that, by Claim 10, $e \subseteq W_i$, for some $i \in \{1, \ldots, k\}$ thus we have $\hat{z}_e = z^\alpha_i = \prod_{v \in e} z^\alpha_i$. If $w_i \notin e$, then $z^\omega_{w_i} = \bar{z}_v$, for every $v \in e$, then $\hat{z}_e = \prod_{v \in e} \bar{z}_v$. Otherwise, if $w_i \in e$, we have that $z^\omega_{w_i} = z^\alpha_{w_i}$, hence $\hat{z}_e = \prod_{v \in e \setminus \{w_i\}} z^\alpha_{w_i} = \prod_{v \in e} \hat{z}_v$.

We now proceed with the proof of the statement of the theorem. The inclusion $\text{conv} S_G \subseteq \text{conv} S_{G_\alpha} \cap \text{conv} S_{G_\omega}$ clearly holds, since $S_G \subseteq S_{G_\alpha} \cap S_{G_\omega}$. Thus, it suffices to show the reverse inclusion. Let $\hat{z} \in \text{conv} S_{G_\alpha} \cap \text{conv} S_{G_\omega}$. We will show that $\hat{z} \in \text{conv} S_G$.

By assumption, the vector $(\hat{z}_0, \hat{z}_1, \ldots, \hat{z}_k, \hat{z}_{\bar{k}})$ is in $\text{conv} S_{G_\alpha}$. Thus, it can be written as a convex combination of points in $S_{G_\alpha}$; i.e., there exists $\mu \geq 0$ with $\sum_{\alpha \in A} \mu_\alpha = 1$ such that

$$(\hat{z}_0, \hat{z}_1, \ldots, \hat{z}_k, \hat{z}_{\bar{k}}) = \sum_{\alpha \in A} \mu_\alpha (z^\alpha_0, z^\alpha_1, \ldots, z^\alpha_k, z^\alpha_{\bar{k}+1}), \quad (53)$$

where the vectors $(z^\alpha_0, z^\alpha_1, \ldots, z^\alpha_k, z^\alpha_{\bar{k}+1})$, for $\alpha \in A$, belong to $S_{G_\alpha}$. For each $i = 1, \ldots, k$, we partition the index set $A$ into $A^{i,0} \cup A^{i,1}$, where $\alpha \in A^{i,1}$ if and only if $z^\alpha_{w_i} = 1$. Similarly, the vector $(\hat{z}_{\bar{k}}, \hat{z}_{\bar{k}+1})$ in $\text{conv} S_{G_\omega}$ and it can be written as a convex combination of points in $S_{G_\omega}$; i.e., there exists $\nu \geq 0$ with $\sum_{\omega \in \Omega} \nu_\omega = 1$ such that

$$(\hat{z}_{\bar{k}}, \hat{z}_{\bar{k}+1}) = \sum_{\omega \in \Omega} \nu_\omega (z^\omega_{\bar{k}}, z^\omega_{\bar{k}+1}), \quad (54)$$

where the vectors $(z^\omega_{\bar{k}}, z^\omega_{\bar{k}+1})$, for $\omega \in \Omega$, belong to $S_{G_\omega}$. We partition the index set $\Omega$ differently to how we partition $A$. Namely, we partition $\Omega$ into $\Omega^T$, for $T \subseteq \bar{p}$, when $\omega \in \Omega^T$ if and only if for every $v \in \bar{p}$ we have $z^\omega_v = 1$ if and only if for $v \in T$.

We now obtain some relations between the multipliers $\mu$, $\nu$, and the vector $\hat{z}$ that will be used in the remainder of the proof. By considering the component of $(53)$ and of $(54)$ corresponding to $\bar{p}$ we obtain

$$\hat{z}_\bar{p} = \sum_{\alpha \in A^{1,1} \cap \cdots \cap A^{k,1}} \mu_\alpha = \sum_{\omega \in \Omega^\bar{p}} \nu_\omega, \quad (55)$$

By considering the component of $(53)$ and of $(54)$ corresponding to $w_i$, for $i = 1, \ldots, k$, we obtain

$$\hat{z}_{w_i} = \sum_{\alpha \in A^{i,1}} \mu_\alpha = \sum_{T \subseteq \bar{p} \cap w_i \cap T} \nu_\omega, \quad (55)$$

By considering the component of $(53)$ and of $(54)$ corresponding to $\omega$, for $i = 1, \ldots, k$, we obtain

$$\hat{z}_{w_i} = \sum_{\alpha \in A^{i,0}} \mu_\alpha = \sum_{T \subseteq \bar{p} \cap \omega \cap T} \nu_\omega.$$
By defining, for $T \subset \bar{\rho}$,
\[
\rho_T(w_i) := \begin{cases} 
\hat{z}_{w_i} - \hat{z}_{\bar{\rho}} & \text{if } w_i \in T, \\
1 - \hat{z}_{w_i} & \text{if } w_i \notin T,
\end{cases} \quad \rho(T) := \prod_{i=1}^{k} \rho_T(w_i), \tag{56}
\]
we obtain the following relation regarding multipliers $\mu$:
\[
\sum_{\alpha \in A^{1,\chi_T(w_i)} \setminus \{A^{1,1} \cap \cdots \cap A^{k,1}\}} \mu_{\alpha} = \rho_T(w_i). \tag{57}
\]
For multipliers $\nu$ we derive
\[
\sum_{T \subseteq \beta: w_i \in T, \omega \in \Omega^T} \nu_{\omega} = \sum_{T \subseteq \beta: w_i \in T, \omega \in \Omega^T} \nu_{\omega} - \sum_{\omega \in \Omega^p} \nu_{\omega} = \hat{z}_{w_i} - \hat{z}_{\bar{\rho}},
\]
\[
\sum_{T \subseteq \beta: w_i \notin T, \omega \in \Omega^T} \nu_{\omega} = \sum_{T \subseteq \beta: w_i \notin T, \omega \in \Omega^T} \nu_{\omega} = 1 - \hat{z}_{w_i}. \tag{58}
\]

For every $\alpha \in A^{1,1} \cap \cdots \cap A^{k,1}$ and $\omega \in \Omega^p$, we denote by $z^0, \omega := (z_0^1, z_1^1, \ldots, z_k^1, z_0^\omega, z_1^\omega, \ldots, z_k^\omega)$, which is in $S_G$ by Claim [11]. For every $\beta \subseteq \bar{\rho}$, $\alpha_i \in A_i^{1,\chi_T(w_i)} \setminus \{A^{1,1} \cap \cdots \cap A^{k,1}\}$, for $i = 1, \ldots, k$, and $\omega \in \Omega^T$, we denote by $z^{\alpha_1, \ldots, \alpha_k, \omega} := (z_0^{\alpha_1}, z_1^{\alpha_1}, z_2^{\alpha_2}, \ldots, z_k^1, z_0^\omega, z_1^\omega, \ldots, z_k^\omega)$. Note that the vector $z^{\alpha_1, \ldots, \alpha_k, \omega}$ is in $S_G$ by Claim [12].

**Claim 13.** The vector $\hat{z}$ can be written as $\hat{z}_\beta \hat{z}^1 + (1 - \hat{z}_\beta) \hat{z}^0$, where $\hat{z}^1$ and $\hat{z}^0$ are defined as the following convex combination of vectors in $S_G$:
\[
\hat{z}^1 := \sum_{\omega \in \Omega^p} \frac{\mu_{\alpha} \nu_{\omega}}{(\hat{z}_\beta)^2} \cdot z^{\alpha, \omega}, \tag{59}
\]
\[
\hat{z}^0 := \sum_{T \subseteq \beta, \omega \in \Omega^T, \alpha_1, \ldots, \alpha_k \in A_i^{1,\chi_T(w_i)} \setminus \{A^{1,1} \cap \cdots \cap A^{k,1}\}} \frac{\mu_{\alpha_1} \cdots \mu_{\alpha_k} \nu_{\omega}}{(1 - \hat{z}_\beta) \rho(T)} \cdot z^{\alpha_1, \ldots, \alpha_k, \omega}. \tag{60}
\]

**Proof of claim.** Note that all the multipliers are nonnegative. We verify that they sum up to one. First consider the multipliers in (59). We obtain
\[
\sum_{\omega \in \Omega^p} \frac{\mu_{\alpha} \nu_{\omega}}{(\hat{z}_\beta)^2} = \frac{1}{(\hat{z}_\beta)^2} \cdot \sum_{\omega \in \Omega^p} \nu_{\omega} \cdot \sum_{\alpha \in A^{1,1} \cap \cdots \cap A^{k,1}} \mu_{\alpha} = 1,
\]
where the last equation follows from (55). Next consider the multipliers in (60). We have
\[
\sum_{T \subseteq \beta, \omega \in \Omega^T, \alpha_1, \ldots, \alpha_k \in A_i^{1,\chi_T(w_i)} \setminus \{A^{1,1} \cap \cdots \cap A^{k,1}\}} \frac{\mu_{\alpha_1} \cdots \mu_{\alpha_k} \nu_{\omega}}{(1 - \hat{z}_\beta) \rho(T)} = \frac{1}{1 - \hat{z}_\beta} \cdot \sum_{T \subseteq \beta, \omega \in \Omega^T} \nu_{\omega} \cdot \rho(T) \cdot \prod_{i=1}^{k} \left( \sum_{\alpha_i \in A_i^{1,\chi_T(w_i)} \setminus \{A^{1,1} \cap \cdots \cap A^{k,1}\}} \mu_{\alpha_i} \right) = \frac{1}{1 - \hat{z}_\beta} \cdot \sum_{T \subseteq \beta, \omega \in \Omega^T} \nu_{\omega} = 1,
\]
where the second equation holds by (56) and (57), and the last equation follows from (55).

In the remainder of the proof we show that \( \hat{z}_p \hat{z}^1 + (1 - \hat{z}_p) \hat{z}^0 = \hat{z} \). First, we consider components \( \bullet \in \{ \cap, k + 1 \} \). We calculate \( \hat{z}_p \hat{z}^1 \) using (59).

\[
\hat{z}_p \hat{z}^1 = \frac{1}{\hat{z}_p} \cdot \sum_{\omega \in \Omega^p, \alpha \in A^{1,1} \cap \cdots \cap A^{k,1}} \mu_\alpha \nu_\omega z^\omega = \frac{1}{\hat{z}_p} \cdot \sum_{\omega \in \Omega^p} \nu_\omega z^\omega \cdot \sum_{\alpha \in A^{1,1} \cap \cdots \cap A^{k,1}} \mu_\alpha = \sum_{\omega \in \Omega^p} \nu_\omega z^\omega,
\]

where the last equation holds by (55). Next, we calculate \( (1 - \hat{z}_p) \hat{z}^0 \) using (60).

\[
(1 - \hat{z}_p) \hat{z}^0 = \sum_{T \subset p, \omega \in \Omega^T} \sum_{\alpha_i \in A^{i,\chi_T(w_i)} \setminus \{A^{1,1} \cap \cdots \cap A^{k,1}\}, i = 1, \ldots, k} \frac{\mu_{\alpha_1} \cdots \mu_{\alpha_k} \nu_\omega}{\rho(T)} \cdot z^\omega = \sum_{T \subset p, \omega \in \Omega^T} \nu_\omega z^\omega = \sum_{\omega \in \Omega} \nu_\omega z^\omega = \hat{z}_p \hat{z}^0,
\]

where in the third equation we used (56) and (57). We obtain that

\[
\hat{z}_p \hat{z}^1 + (1 - \hat{z}_p) \hat{z}^0 = \sum_{\omega \in \Omega^p} \nu_\omega z^\omega + \sum_{T \subset p, \omega \in \Omega^T} \nu_\omega z^\omega = \sum_{\omega \in \Omega} \nu_\omega z^\omega = \hat{z}_p \hat{z}^1, \quad \text{where in the last equation we used (54).}
\]

To simplify our calculation of \( \hat{z}_p \hat{z}^1 + (1 - \hat{z}_p) \hat{z}^0 \) for the remaining components \( \bullet \in \{ 0, 1, \ldots, k \} \), we calculate \( \hat{z}_p \hat{z}^1 \) using (59). We obtain

\[
\hat{z}_p \hat{z}^1 = \frac{1}{\hat{z}_p} \cdot \sum_{\omega \in \Omega^p, \alpha \in A^{1,1} \cap \cdots \cap A^{k,1}} \mu_\alpha \nu_\omega z^\alpha = \frac{1}{\hat{z}_p} \cdot \sum_{\alpha \in A^{1,1} \cap \cdots \cap A^{k,1}} \mu_\alpha \sum_{\omega \in \Omega^p} \nu_\omega z^\alpha = \sum_{\alpha \in A^{1,1} \cap \cdots \cap A^{k,1}} \mu_\alpha z^\alpha, \quad (61)
\]

where the last equation holds by (55).

We now consider the components \( z_0 \) and we show that \( \hat{z}_p \hat{z}^1_0 + (1 - \hat{z}_p) \hat{z}^0_0 = \hat{z}_0 \). We will be using the fact that for each \( \alpha \in A \setminus \{ A^{1,1} \cap \cdots \cap A^{k,1} \} \), we have that \( z_0^\alpha = 0 \) since each component corresponds to an edge that strictly contains edge \( \bar{p} \) and at least one node in \( \bar{p} \) has its component in \( z_0^\alpha \) equal to zero. First we show that \( \hat{z}^0 = 0 \). For each vector \( z_0^{\alpha_1, \ldots, \alpha_k, \omega} = z_0^{\alpha_1} \) and \( A^{\alpha_1, \ldots, \alpha_k, \omega} \in A \setminus \{ A^{1,1} \cap \cdots \cap A^{k,1} \} \), thus \( z_0^{\alpha_1, \ldots, \alpha_k, \omega} = 0 \) and \( z_0^0 = 0 \). We obtain

\[
\hat{z}_p \hat{z}^1_0 + (1 - \hat{z}_p) \hat{z}^0_0 = \hat{z}_p \hat{z}^1_0 = \sum_{\alpha \in A^{1,1} \cap \cdots \cap A^{k,1}} \mu_\alpha z_0^\alpha = \sum_{\alpha \in A} \mu_\alpha z_0^\alpha = \hat{z}_0,
\]

where the second equation holds by (61), and the third equation follows by the observation above.

Finally, we consider the components \( z_j \), for \( j = 1, \ldots, k \), and we show that \( \hat{z}_p \hat{z}^1_j + (1 - \hat{z}_p) \hat{z}^0_j = \hat{z}_j \).
We calculate \((1 - \bar{z}_p)^{z_0}_j\) using (61).

\[
(1 - \bar{z}_p)^{z_0}_j = \sum_{T \subset \hat{p}, \omega \in \Omega^T, \alpha_1 \in \hat{A}^{1 \times T(w_j)} \setminus \{A^{1 \times \cdots \times A^{k}}\}, i=1, \ldots, k} \frac{\mu_{\alpha_1} \cdots \mu_{\alpha_k} \nu_{\omega}}{\rho(T)} \cdot \bar{z}_j
\]

\[
= \sum_{T \subset \hat{p}, \omega \in \Omega^T, \alpha_j \in \hat{A}^{1 \times T(w_j)} \setminus \{A^{1 \times \cdots \times A^{k}}\}, \alpha_j \in \hat{A}^{1 \times T(w_j)} \setminus \{A^{1 \times \cdots \times A^{k}}\}, i=1, \ldots, k} \frac{\mu_{\alpha_j} \nu_{\omega}}{\rho_T(w_j)} \cdot \bar{z}_j
\]

\[
= \sum_{T \subset \hat{p}, \omega \in \Omega^T, \alpha_j \in \hat{A}^{1 \times T(w_j)} \setminus \{A^{1 \times \cdots \times A^{k}}\}, \omega \in \Omega^T, \alpha_j \in \hat{A}^{1 \times T(w_j)} \setminus \{A^{1 \times \cdots \times A^{k}}\}, i=1, \ldots, k} \frac{\mu_{\alpha_j} \nu_{\omega}}{1 - \bar{z}_j} \cdot \bar{z}_j
\]

\[
= \frac{1}{\bar{z}_j} \cdot \sum_{\alpha_j \in \hat{A}^{1 \times T(w_j)} \setminus \{A^{1 \times \cdots \times A^{k}}\}} \mu_{\alpha_j} \bar{z}_j
\]

\[
= \sum_{\alpha_j \in \hat{A}^{1 \times T(w_j)} \setminus \{A^{1 \times \cdots \times A^{k}}\}} \mu_{\alpha_j} \bar{z}_j
\]

where in the third equation we used (56) and (57), in the fourth equation we used the definition of \(\rho_T(w_j)\) in (56), and in the sixth equation we used (68). Using the obtained expression and (61), we have that \(\bar{z}_p \bar{z}_j + (1 - \bar{z}_p)^{z_0}_j\) equals

\[
\sum_{\alpha_j \in \hat{A}^{1 \times T(w_j)} \setminus \{A^{1 \times \cdots \times A^{k}}\}} \mu_{\alpha_j} \bar{z}_j
\]

where the last equation follows by (53).

\[\square\]

5.3 Proof of Theorem 3

Let \(G = (V, E)\) be a kite-free \(\beta\)-acyclic hypergraph. The proof is by induction on the number of maximal edges of \(G\). If \(G\) has one maximal edge, then the proof follows from by Lemmata 3 and 7 and Corollary 3. Hence suppose that \(G\) has \(\kappa\) maximal edges for some \(\kappa \geq 2\). By Lemma 4, there exists a running intersection ordering \(O\) of the set of maximal edges of \(G\).

Lifting and decomposition. Denote by \(\bar{\epsilon}\) the last element of \(O\) and define \(\bar{\mu} := N(\bar{\epsilon})\). Let \(G^+ = (V, E^+)\) be the hypergraph obtained from \(G\) by adding \(\bar{\mu}\) to \(E\) if \(\bar{\mu} \notin V \cup E\); that is, let \(E^+ = E \cup \{\bar{\mu}\}\) if \(\bar{\mu} \notin V \cup E\) and let \(E^+ = E\), otherwise. Denote by \(G_{\alpha}\) the section hypergraph of \(G^+\) induced by \(\bar{\mu}\), and denote by \(G_{\omega}\) the section hypergraph of \(G\) induced by \(\cup \{E^+ \setminus E(G_{\alpha})\}\). As we detailed in the proof of Theorem 2 by Theorem 1, the multilinear set \(S_{G^+}\) is decomposable into multilinear sets \(S_{G_{\alpha}}\) and \(S_{G_{\omega}}\). As we argued in the proof of Theorem 2, \(G_{\alpha}\) is a 2-laminar \(\beta\)-acyclic hypergraph. Hence, by Corollary 3 we have \(MP_{G_{\alpha}} = MP_{G_{\alpha}}^{RI}\).
Now consider the hypergraph $G_\omega$. First note that $G_\omega$ has $\kappa - 1$ maximal edges that are different from $\tilde{e}$. We show that $G_\omega$ is a kite-free $\beta$-acyclic hypergraph. If $\tilde{p} \in V \cup \overline{E}$, then $G_\omega$ is a partial hypergraph of $G$ and hence the statement follows trivially. Hence, suppose that $\tilde{p} \notin V \cup \overline{E}$. It is simple to see that $G_\omega$ is the subhypergraph of $G$ induced by $\bigcup_{e \in \overline{E}} e$, where $\overline{E}$ denotes the set of maximal edges of $G$. Since $G$ is $\beta$-acyclic, by Lemma 3, $G_\omega$ is $\beta$-acyclic as well. To show that $G_\omega$ is kite-free, we need to show that exist no three edges $e_0, e_1, e_2 \in E(G_\omega)$ such that $|e_0 \cap e_1 \cap e_2| \geq 2$, $(e_0 \cap e_1) \setminus e_2 \neq \emptyset$, and $(e_0 \cap e_2) \setminus e_1 \neq \emptyset$. To obtain a contradiction, suppose that such three edges exist. Again, one of these edges, say $e_0$, must be the edge $\tilde{p}$, since by assumption $G$ is kite-free. Since $\tilde{e} \cap \bigcup_{e \in \overline{E}(G_\omega)} e = \tilde{p}$, it follows that, the three edges $\tilde{e}, e_1$ and $e_2$ in $G$ satisfy $|\tilde{e} \cap e_1 \cap e_2| \geq 2$, $(\tilde{e} \cap e_1) \setminus e_2 \neq \emptyset$, and $(\tilde{e} \cap e_2) \setminus e_1 \neq \emptyset$, which is in contradiction with the assumption that $G$ is kite-free. Hence, $G_\omega$ is a kite-free $\beta$-acyclic hypergraph and by the induction hypothesis we have $MP_{G_\omega} = MP_{RI}^{G_\omega}$, which together with $MP_{G_\alpha} = MP_{RI}^{G_\alpha}$ and the decomposability of $S_G$ into $S_{G_\alpha}$ and $S_{G_\omega}$, implies $MP_{G^+} = MP_{RI}^{G^+}$.

If $G = G^+$; that is if $\tilde{p} \in V \cup \overline{E}$, we obtain $MP_G = MP_{RI}^G$ and this completes the proof. Henceforth, assume that $\tilde{p} \notin V \cup \overline{E}$. To obtain $MP_G$, it suffices to project out the auxiliary variable $z_{\tilde{p}}$ from the facet-description of $MP_{G^+}$. In the following, we perform this projection using Fourier–Motzkin elimination.

**Projection.** First consider an inequality in the description of $MP_{RI}^{G^+}$ that does not contain $z_{\tilde{p}}$. Clearly, the support hypergraph of such an inequality is a partial hypergraph of $G$. The following claim establishes that this inequality is also present in the description $MP_{RI}^G$.

**Claim 14.** Let $G'$ be a partial hypergraph of $G$. Then all inequalities defining $MP_{RI}^{G'}$ are also present in the system defining $MP_{RI}^{G}$.

**Proof of claim.** Clearly, $MP_{LP}^G$ contains all inequalities present in the description of $MP_{LP}^{G'}$, since the standard linearization of a multilinear set is obtained by intersecting the multilinear polytopes of each edge of the corresponding hypergraph and we have $E(G') \subset E(G)$. In addition, by definition of running intersection inequalities, every running intersection inequality for $S_{G'}$ is a running intersection inequality for $S_G$, as again $E(G') \subset E(G)$. Hence, all inequalities defining $MP_{RI}^{G'}$ are also present in $MP_{RI}^{G}$. \hfill ∅

To complete the proof, we need to show that by projecting out $z_{\tilde{p}}$ from the remaining inequalities of $MP_{RI}^{G^+}$, we obtain valid inequalities for $MP_{RI}^{G}$. First, consider $MP_{G_\alpha}$; denote by $\tilde{e}$ the edge of $G_\alpha$ such that $\tilde{p} \in I(\tilde{e})$; the uniqueness of $\tilde{e}$ follows from the fact that $G_\alpha$ is a 2-laminar hypergraph. By Proposition 3, $z_{\tilde{p}}$ appears in the following inequalities, which we will refer to as system (I) in the rest of the proof:

\begin{align}
-z_{\tilde{p}} + z_{\tilde{e}} &\leq 0 \quad \forall \tilde{p} \in I(\tilde{e}) \tag{62} \\
-z_{\tilde{p}} + z_{\tilde{e}} &\leq 0 \tag{63} \\
\sum_{v \in \tilde{p}} (1 - \delta_{\tilde{p}}(v))z_v + \sum_{e \in I(\tilde{e}) \cap \overline{E}} z_e - z_{\tilde{p}} &\leq \omega(\tilde{p}) - 1 \tag{64} \\
\sum_{v \in \tilde{e}} (1 - \delta_{\tilde{e}}(v))z_v + \sum_{e \in I(\tilde{e}) \cap \overline{E}} z_e - z_{\tilde{e}} &\leq \omega(\tilde{e}) - 1. \tag{65}
\end{align}

Now consider the polytope $MP_{G_\omega} = MP_{RI}^{G_\omega}$. As we showed earlier, $G_\omega$ is a kite-free $\beta$-acyclic hypergraph. Hence, its running intersection inequalities are of the form (10). Let $E_{\tilde{p}}$ be the set containing all subsets of edges $E_{\tilde{p}}$ in $G_\omega$ such that the center edge $\tilde{p}$ together with neighbors
e, \forall e \in E_\beta satisfy Conditions (i) and (ii) of Proposition 3. Note that \( E_\beta \) contains the empty set. Let \( \hat{E} \) denote the set of all edges \( \hat{e} \) of \( G_\omega \) such that \( |\hat{e} \cap e| \geq 2 \). For each \( \hat{e} \in \hat{E} \), denote by \( E_{\hat{e}} \) the set containing all subsets of edges \( E_{\hat{e}} \) in \( G_\omega \) such that \( \bar{p} \in E_{\hat{e}} \) and the center edge \( \hat{e} \) with neighbors \( e, \forall e \in E_{\hat{e}} \) satisfy Conditions (i) and (ii) of Proposition 3. Denote by \( \omega(E_{\hat{e}}) \) the number of connected components in the hypergraph with the node set \( \bar{p} \) (resp. \( \hat{e} \)) and the edge set \( \{\bar{p} \cap e, \forall e \in E_{\hat{e}}\} \) (resp. \( \{\hat{e} \cap e, \forall e \in E_{\hat{e}}\} \)). Finally, for each \( v \in \bar{p} \) (resp. \( v \in \hat{e} \)) denote by \( \delta_E(v) \) (resp. \( \delta_{\hat{e}}(v) \)) the number of edges in \( E_\beta \) (resp. \( E_{\hat{e}} \)) containing \( v \). Then, the inequalities of \( MP_{RI}^{\omega} \) containing \( z_\beta \) are given by:

\[
-z_\beta + z_\beta \leq 0 \quad \forall p \in I(\bar{p}) \tag{66}
\]

\[
\sum_{v \in \bar{p}} (1 - \delta_E(v))z_v + \sum_{e \in E_\beta} z_e - z_\beta \leq \omega(E_\beta) - 1 \quad \forall E_\beta \in E_\beta \tag{67}
\]

\[
\sum_{v \in \hat{e}} (1 - \delta_{\hat{e}}(v))z_v + \sum_{e \in E_{\hat{e}}} z_e - z_\hat{e} \leq \omega(E_{\hat{e}}) - 1 \quad \forall \hat{e} \in \hat{E}, \forall E_{\hat{e}} \in E_{\hat{e}}. \tag{68}
\]

In the remainder of the proof, we will refer to the inequalities \( (66) \)–\( (68) \) as system (II).

Now consider the system of linear inequalities (I)–(II). We eliminate \( z_\beta \) from this system using Fourier–Motzkin elimination. First suppose that we select two inequalities from system (I). Denote by \( G_\alpha' \) the hypergraph obtained by removing the edge \( p \) from \( G_\alpha \). It then follows that the inequality \( az \leq \alpha \) obtained as a result of such projection is valid for \( MP_{RI}^{G_\alpha} \). Since \( G_\alpha' \) is a 2- laminar \( \beta \)-acyclic hypergraph, by Corollary 3, we have \( MP_{RI}^{G_\alpha'} = MP_{RI}^{G_\omega} \). Finally, since \( G_\alpha' \) is a partial hypergraph of \( G \), by Claim 11, \( az \leq \alpha \) is a valid inequality for \( MP_{RI}^{G_\omega} \). Similarly, we argue that by projecting out \( z_\beta \) from two inequalities of system (II), we obtain an inequality that is valid for \( MP_{RI}^{G_\omega} \). To see this, observe that the hypergraph \( G_\omega' \) obtained by removing \( \bar{p} \) from \( G_\omega \) is kite-free, \( \beta \)-acyclic, and has \( \kappa - 1 \) maximal edges for which by the induction hypothesis we have \( MP_{RI}^{G_\omega} = MP_{RI}^{G_\omega'}. \) Therefore, it suffices to examine inequalities obtained by projecting out \( z_\beta \) starting from two inequalities one of which is only present in system (I) while the other one is only present in system (II).

We start by selecting one inequality in \( (62) \) from system (I). Clearly, this inequality is identical to inequality \( (66) \) present in system (II). Hence, by the above discussion, we do not need to consider inequalities \( (62) \). Next, consider inequality \( (63) \) from system (I). Since the coefficient of \( z_\beta \) in \( (63) \) is negative, it suffices to consider inequalities \( (66) \) and \( (68) \) from system (II). In addition, we do not need to consider \( (66) \) since it is already present in system (II). By summing inequalities \( (65) \) and \( (68) \), for each \( \hat{e} \in \hat{E} \) and each \( E_{\hat{e}} \in E_{\hat{e}} \) we obtain

\[
\sum_{v \in \hat{e}} (1 - \delta_{\hat{e}}(v))z_v + \sum_{e \in E_{\hat{e}} \setminus \{\beta\}} z_e + z_\hat{e} - z_\hat{e} \leq \omega(E_{\hat{e}}) - 1. \tag{69}
\]

We claim that inequality \( (69) \) is a running intersection inequality of the form \( (19) \) centered at \( \hat{e} \) with neighbors \( E_{\hat{e}} := (E_\hat{e} \setminus \{\beta\}) \cup \{\hat{e}\} \). As before, let \( \delta_{E_{\hat{e}}}(v) \) denote the number of edges in \( E_{\hat{e}} \) containing the node \( v \in \hat{e} \) and denote by \( \omega(E_{\hat{e}}) \) the number of connected components in the hypergraph with the node set \( \hat{e} \) and the edge set \( \{\hat{e} \cap e, \forall e \in E_{\hat{e}}\} \). For each \( \hat{e} \in \hat{E} \) and each \( E_{\hat{e}} \in E_{\hat{e}} \), we have \( \hat{e} \cap \bar{p} = \hat{e} \cap \bar{e} \) and \( e \cap \bar{p} = e \cap \bar{e} \) for all \( e \in E_{\hat{e}} \), as by definition \( \bar{p} = N(\hat{e}), \hat{e} \subseteq \hat{e}, \hat{e} \supseteq \bar{p}, \hat{e} \not\subseteq \bar{e}, \) and \( e \not\subseteq \bar{e} \) for all \( e \in E_{\hat{e}} \). This implies that conditions (i) and (ii) of Proposition 3 are satisfied for \( \hat{e}, e \in E_{\hat{e}} \). Moreover, \( \delta_{E_{\hat{e}}}(v) = \delta_{E_{\hat{e}}}(v) \) for all \( v \in \hat{e} \) and \( \omega(E_{\hat{e}}) = \omega(E_{\hat{e}}) \). It then follows that for each \( \hat{e} \in \hat{E} \) and each \( E_{\hat{e}} \in E_{\hat{e}} \), inequality \( (69) \) is a running intersection inequality of the form \( (19) \) is therefore present in \( MP_{RI}^{G_\omega} \).

By construction, there exists a set \( E_\beta \in E_\beta \) such that \( E_{\hat{e}} = I(\bar{p}) \cap E \). Therefore, inequalities \( (64) \) are implied by inequalities \( (67) \) and as a result we do not need to consider these inequalities. Hence
we proceed with inequalities (65) from system (I). Since the coefficient of $z_p$ in (65) is positive, it suffices to consider inequalities (67) from system (II). By summing inequalities (65) and (67), for each $E_p \in \mathcal{E}_p$ and defining $E_e := E_p \cup ((I(\bar{e}) \setminus \{\bar{p}\}) \cap E)$, we get:

$$
\sum_{v \in \bar{e}} (1 - \delta_{E_e}(v))z_v + \sum_{v \in \bar{p}} (1 - \delta_{E_p}(v))z_v + \sum_{e \in E_{\bar{e}}} z_e - z_{\bar{e}} \leq \omega(\bar{e}) + \omega(E_p) - 2.
$$

(70)

For each $v \in \bar{e}$, denote by $\delta_{E_e}(v)$ the number of edges in $E_{\bar{e}}$ containing $v$ and denote by $\omega(E_{\bar{e}})$ the number of connected components of the hypergraph $(\bar{e}, \bar{E})$, where $\bar{E} = \{e \cap \bar{e} : e \in E_p\}$. It can be checked that $\omega(E_{\bar{e}}) = \omega(\bar{e}) + \omega(E_p) - 1$. Clearly, for any node $v \in \bar{e} \setminus \bar{p}$ we have $\delta_{E_e}(v) = \delta_{E_p}(v)$. Now consider a node $v \in \bar{p}$; since $\bar{p} \in I(\bar{e})$ but $\bar{p} \notin E_{\bar{e}}$, we have $\delta_{E_e}(v) = \delta_{E_p}(v) + \delta_{E_p}(v) - 1$. Since $\bar{e} \supset \bar{p}$, inequality (70) can be equivalently written as

$$
\sum_{v \in \bar{e}} (1 - \delta_{E_e}(v))z_v + \sum_{e \in E_{\bar{e}}} z_e - z_{\bar{e}} \leq \omega(E_{\bar{e}}) - 1.
$$

(71)

To complete the proof, we need to show that $\bar{e}, e : e \in E_{\bar{e}}$ satisfy conditions (i) and (ii) of Proposition 3; condition (i) is clearly satisfied as $\bar{e} \supset e$ for all $e \in I(\bar{e}) \cap E$ and $|\bar{e} \cap e| \geq 2$ for all $e \in E_p$ since $|\bar{p} \cap e| \geq 2$ for all $e \in E_p$ and $\bar{e} \supset \bar{p}$. To demonstrate the validity of Condition (ii), we need to show that $e \cap \bar{e} \subseteq e' \cap \bar{e}$ for all $e', e \in E_{\bar{e}}$. By definition $|e \cap e'| \leq 1$ for all $e, e' \in I(\bar{e}) \cap E$; moreover, by construction $e \cap \bar{e} = e' \cap \bar{e}$ for all $e \in E_p$ and $e \cap \bar{e} \subseteq e' \cap \bar{e}$ for all $e, e' \in E_p$. Finally $|e \cap e'| \leq 1$ for all $e \in (I(\bar{e}) \setminus \{\bar{p}\}) \cap E$ and for all $e' \in E_p$ as $|e \cap \bar{p}| \leq 1$ for all $e \in (I(\bar{e}) \setminus \{\bar{p}\}) \cap E$ and by definition $\bar{p} = N(\bar{e})$. Therefore, for each $E_p \in \mathcal{E}_p$, inequality (71) is a running intersection inequality of the form (19) centered at $\bar{e}$ with neighbors $e, e \in E_{\bar{e}}$ and hence is present in $\text{MP}^\mathcal{E}_p\mathcal{R}_\mathcal{E}^\mathcal{E}_p$.
