Abstract

In 1988, Barzilai and Borwein published a pioneering paper which opened the way to inexpensively accelerate first-order methods. More in detail, in the framework of unconstrained optimization, Barzilai and Borwein developed two strategies to select the steplength in gradient descent methods with the aim of encoding some second-order information of the problem without computing and/or employing the Hessian matrix of the objective function.

Starting from these ideas, several efficient steplength techniques have been suggested in the last decades in order to make gradient descent methods more and more appealing also for problems which handle large-scale data and require real-time solutions. Typically, these new steplength selection rules have been tuned in the quadratic unconstrained framework for sweeping the spectrum of the inverse of the Hessian matrix, and then applied also to non-quadratic constrained problems, without any substantial modification, by showing to be very effective anyway.

In this paper we deeply analyse how, in quadratic and non-quadratic minimization problems, the presence of a feasible region, expressed by a single linear equality constraint together with lower and upper bounds, influences the spectral properties of the original Barzilai-Borwein (BB) rules, generalizing recent results provided for box-constrained quadratic problems. This analysis gives rise to modified BB approaches able not only to capture second-order information but also to exploit the nature of the feasible region. We show the benefits gained by the new steplength rules on a set of test problems arising also from machine learning and image processing applications.

Keywords: Singly Linearly and bound constrained optimization, gradient projection methods, steplength rules, Hessian spectral properties

1. Introduction

In this paper we are interested in solving the following singly linearly equality constrained problem subject to lower and upper bounds

\[ \min_{x \in \mathbb{R}^n} f(x) \]
subject to \( \ell \leq x \leq u \quad v^T x = e \]

where \( \ell, u \) and \( v \) are vectors of \( \mathbb{R}^n \) and \( e \) is a scalar. We assume that the feasible region \( \Omega = \{ x \in \mathbb{R}^n : \ell \leq x \leq u, v^T x = e \} \) is not empty. We refer to (1) as the general SLB problem. The study of this minimization model is quite relevant since it allows to formalize real-life applications in different areas, such as imaging, signal processing, machine learning and portfolio optimization (see for example [4, 5, 31, 41, 37]). Since a common feature of these applications lies in their large-scale, among all the iterative schemes which can be selected to solve the corresponding optimization problem, the class of gradient projection methods is very attractive thanks to a simple implementation and a low computational cost per iteration. In this work we consider the so-called gradient projection (GP) method along the feasible direction [3] Chapter 2] whose standard iteration can be written as

\[
d(k) = \Pi_G \left( x^{(k)} - \alpha_k \nabla f(x^{(k)}) \right) - x^{(k)},
\]

\[
x^{(k+1)} = x^{(k)} + \nu_k d(k),
\]

where \( \Pi_G(\cdot) \) denotes the Euclidean projection onto the constraints of (1), \( \alpha_k \) is a positive parameter controlling the step along the negative gradient and \( \nu_k \in (0, 1] \) is a linesearch parameter ensuring a sufficient decrease of the objective function along the direction \( d(k) \), e.g. by means of an Armijo rule [6] or its non-monotone version [28]. Despite the merits previously recalled, the GP method (2) can show a poor convergence rate especially when high accurate solutions are required. A possibility to overcome this difficulty consists in properly selecting the steplength \( \alpha_k \) which simply needs to belong to a compact set \( [\alpha_{\text{min}}, \alpha_{\text{max}}] \), \( 0 < \alpha_{\text{min}} \leq \alpha_{\text{max}} \), in order to guarantee the convergence of the iterative scheme [7]. The literature of the last decades provides many attempts to exploit this freedom of choice for \( \alpha_k \) with the aim of accelerating the convergence of the gradient methods. The paper [2] which firstly suggests the key ideas to fully take advantage of the presence of the steplength \( \alpha_k \) has been published in 1988 by Barzilai and Borwein (BB) in the framework of unconstrained optimization. In this paper, the authors force quasi-Newton properties on the diagonal matrix \( (\alpha_k I_n)^{-1} \), where \( I_n \) is the identity matrix of order \( n \), for approximating the Hessian matrix \( \nabla^2 f(x^{(k)}) \). More in detail, the steplength updating rules developed by Barzilai and Borwein have to satisfy the following secant conditions

\[
\alpha_k^{BB1} = \arg \min_{\alpha \in \mathbb{R}} \| \alpha^{-1} s^{(k-1)} - y^{(k-1)} \|, \quad \alpha_k^{BB2} = \arg \min_{\alpha \in \mathbb{R}} \| s^{(k-1)} - \alpha y^{(k-1)} \|,
\]

where \( s^{(k-1)} = x^{(k)} - x^{(k-1)} \) and \( y^{(k-1)} = \nabla f(x^{(k)}) - \nabla f(x^{(k-1)}) \). The resulting values become

\[
\alpha_k^{BB1} = \frac{s^{(k-1)T} s^{(k-1)}}{s^{(k-1)T} y^{(k-1)}}, \quad \alpha_k^{BB2} = \frac{s^{(k-1)T} y^{(k-1)}}{y^{(k-1)T} y^{(k-1)}}.
\]

We recall that, in the case of quadratic objective function with symmetric and positive definite Hessian matrix \( A \), the BB rules [4] provide values belonging to the spectrum of the inverse of \( A \) since they obey to the following property

\[
\frac{1}{\lambda_{\text{max}}(A)} \leq \alpha_k^{BB2} \leq \alpha_k^{BB1} \leq \frac{1}{\lambda_{\text{min}}(A)}
\]

where \( \lambda_{\text{min}}(A) \) and \( \lambda_{\text{max}}(A) \) denote the minimum and the maximum eigenvalues of \( A \), respectively. Starting from the inspiring work of Barzilai and Borwein, many steplength updating strategies have been devised to realize more and more effective gradient methods for unconstrained minimization problems (see for example [17, 19, 20, 26, 27, 34]). We report here the approach suggested in [10] which is a modified version of the scheme developed in [26] and has been proved to be one of the most competitive ideas among the strategies previously recalled. In [10], the authors fixed a steplength selection procedure which properly alternates the BB rules as follows

\[
\alpha_k^{VABB_{\text{min}}} = \begin{cases} \min \{ \alpha_j^{BB2} : j = \max \{ 1, k - m_n \}, \ldots, k \} & \text{if } \frac{\alpha_j^{BB2}}{\alpha_k^{BB1}} < \tau_k \text{ otherwise} \end{cases}
\]
where $m_a$ is a nonnegative integer and $\tau_k$ is updated as
\[
\tau_{k+1} = \begin{cases} 
\frac{\tau_k}{\zeta} & \text{if } \frac{a_{\text{BB2}}^{\text{BOX}}}{s^{(k-1)}} < \tau_k \\
\tau_k \cdot \zeta & \text{otherwise}
\end{cases}
\]
with $\zeta > 1$. By selecting $\tau_k = \tau > 0$ at every iteration in [6], the alternating strategy proposed in [20] can be recovered and the corresponding steplength will be hereafter denoted by $\alpha_{k}^{\text{ABB}_{\text{min}}}$. In [21], by focusing on an unconstrained strictly convex quadratic problem, a spectral analysis of the behaviour of the gradient methods shows that the goodness of a steplength selection rule lies in its ability in effectively sweeping the spectrum of the inverse of the Hessian matrix.

The good results gained in solving unconstrained minimization problems by combining the gradient methods with the BB-like rules encouraged the researchers to exploit these techniques also in gradient projection schemes for constrained problems, by obtaining a great success in different fields [7, 3, 34, 39, 44]. Nevertheless, in these gradient projection approaches, the original BB strategies, and the ones built from them, have been employed without any modification to take into account also the feasible set.

Only very recently [16], a spectral analysis of the BB steplength rules in gradient projection methods for box-constrained strictly convex quadratic problems has been developed. Firstly, the authors observed that
\[
\alpha_{k}^{\text{BB1}} = \frac{\|s^{(k-1)}\|^2}{s^{(k-1)} y^{(k-1)}} = \frac{\|s^{(k-1)}\|^2}{s^{(k-1)} y^{(k-1)}},
\]
where, by still denoting with $\ell$ and $u$ the vectors defining the box constraints,
\[
\mathcal{I}_{k-1} = \mathcal{N} - \mathcal{J}_{k-1}, \quad \mathcal{N} = \{1, \ldots, n\}
\]
\[
\mathcal{J}_{k-1} = \{i \in \mathcal{N} : (x_i^{(k-1)} = \ell_i \wedge x_i^{(k)} = \ell_i) \vee (x_i^{(k-1)} = u_i \wedge x_i^{(k)} = u_i)\}.
\]
Moreover, in view of this consideration and since $\alpha_{k}^{\text{BB2}}$ does not share a similar property, they modified the second BB strategy in the following way
\[
\alpha_{k}^{\text{BOX-BB2}} = \frac{s^{(k-1)}_I y^{(k-1)}_I}{\|y^{(k-1)}_I\|^2},
\]
and refined conditions [5] as
\[
\frac{1}{\lambda_{\text{max}}(A_{\mathcal{I}_{k-1}, \mathcal{I}_{k-1}})} \leq \alpha_{k}^{\text{BOX-BB2}} \leq \alpha_{k}^{\text{BB1}} \leq \frac{1}{\lambda_{\text{min}}(A_{\mathcal{I}_{k-1}, \mathcal{I}_{k-1}})},
\]
by denoting with $A_{\mathcal{I}_{k-1}, \mathcal{I}_{k-1}}$ the submatrix of the Hessian of the objective function given by the intersection of the rows and the columns with indices in $\mathcal{I}_{k-1}$. In other words, $\alpha_{k}^{\text{BB1}}$ and $\alpha_{k}^{\text{BOX-BB2}}$ provide some information about the spectrum of the inverse of the Hessian submatrix whose rows and columns are indexed in $\mathcal{I}_{k-1}$.

The goal of this paper is to continue the analysis carried out in [16] and to understand how the presence of a single linear equality constraint together with lower and upper bounds can modify the spectral properties of the BB step length selection rules. Particularly, in the case of quadratic objective function, we investigate how to generalize inequalities [5] and [10] in order to delineate conditions more faithful to the special feasible region of problem [1]. As a consequence, we suggested a new version of the BB2 scheme which generalizes [9]. Furthermore, in the general non-quadratic case, we study the spectral properties of the considered BB rules providing their interpretation in terms of the Hessian matrices evaluated at the iterates of the gradient projection scheme.

The paper is organized as follows. In Section 2, we develop the spectral analysis of the BB approaches in presence of a strictly convex quadratic SLB problem. The corresponding investigation in the more general non-quadratic framework can be appreciated in Section 3. Section 4 is devoted to the results of the numerical experiments performed on several datasets, both quadratic and non-quadratic. The conclusions are drawn in Section 5.
Notation. In the following, we denote by $O_{r,s}$ the $r \times s$ null matrix ($r, s$ positive integer scalars), by $I_r$ the identity matrix of order $r$; finally $I_C$ is the identity matrix of order $2C$.

2. The quadratic case

We start our analysis from the easier case of a quadratic objective function: the optimization problem we consider in this section has the form

$$\begin{align*}
\min_{x \in \mathbb{R}^n} f(x) &\equiv \frac{1}{2} x^T A x - b^T x + c \\
\text{subject to} &\quad \ell \leq x \leq u \quad v^T x = e
\end{align*}$$

(11)

where $A$ is a symmetric positive definite matrix of order $n$, $b \in \mathbb{R}^n$ and $c \in \mathbb{R}$. Let denote $g(x) = \nabla f(x) = Ax - b$ and by $x^*$ the minimizer of the constrained problem (11). Let $J^*$ be the set of indices in $\mathcal{N} = \{1, \ldots, n\}$ of the active box constraints at $x^*$, that is $x^*_i = \ell_i$ or $x^*_i = u_i$ for all $i \in J^*$, and $\mathcal{I}^* = \mathcal{N} \setminus J^*$ the complement of $J^*$ in $\mathcal{N}$, with cardinality $m = |\mathcal{I}^*|$, $0 \leq m \leq n$. By neglecting the special cases $m = 0$ and $m = n$, we assume that $J^* \neq \emptyset$, $J^* \neq \mathcal{N}$, and that $v$ and the columns of the identity matrix of order $n$ with indices in $J^*$ are linearly independent. Consequently the entries of $v$ corresponding to $\mathcal{I}^*$ are not all equal to zero.

Necessary and sufficient conditions for a feasible $x^*$ to be the minimizer are that there exist $\psi^* \in \mathbb{R}$ and $\mu^*, \nu^* \in \mathbb{R}^n$ such that

$$\begin{align*}
g(x^*) - \psi^* v - \mu^* + \nu^* &= 0, \\
v^T x^* &= e, \\
\mu^* \cdot (x^* - \ell) &= 0, \quad x^* - \ell \geq 0, \quad \mu^* \geq 0, \\
\nu^* \cdot (u - x^*) &= 0, \quad u - x^* \geq 0, \quad \nu^* \geq 0,
\end{align*}$$

(12)

where the products between vectors have to be intended component–wise.

For the sake of simplicity, we assume that the rows/columns of $A$ and the entries of any vector are reordered so that $\mathcal{I}^*$ is related to the first $m$ indices and $J^*$ contains the last $n - m$ indices. In the following we will show the relation between the BB steplength values and the spectrum of special matrices obtained as restriction of the matrix $A$ to subspaces depending on the constraints which become active during the iterative process. To this end, we first introduce the restriction of $A$ to the tangent space of the active constraints at the solution and then we study the properties of the approximations of this matrix available in the iterations of the gradient projection schemes.

2.1. The Hessian matrix restricted to the tangent space of the active constraints at the solution

The tangent space of the active constraints at $x^*$ is defined as

$$\Omega^* = \left\{ x \in \mathbb{R}^n : \left[ O_{n-m,m} \ v^T \right] x = O_{n-m+1,1} \right\} = \text{range} \left( \left[ I_{\mathcal{I}^*} \right] \right) \cap \text{null}(v^T).$$

Taking into account that the dimension of $\Omega^*$ is $(m - 1)$, we introduce the matrix $A^* \in \mathbb{R}^{(m-1)\times(m-1)}$ defined as

$$A^* = \hat{U}^*^T A \hat{U}^*$$

(13)

where $\hat{U}^*$ denotes an $n \times (m - 1)$ matrix whose columns are an orthonormal basis of $\Omega^*$. We call $A^*$ the Hessian matrix restricted to the tangent space of the active constraints at the solution, hereafter named restricted Hessian matrix. In order to characterize the symmetric positive definite matrix $A^*$, we collect some useful results on projection matrices in Lemma 2.1 (see [30]).

**Lemma 2.1.** Let $u$ be a non-zero vector in $\mathbb{R}^m$ and define the matrices $V = uu^T / u^Tu$ and $P = I_m - V$. It holds that
If we consider the orthogonal projection $I$ so that 

$$A$$

In the next subsection we will show that, when a gradient projection method is applied for solving prob-

ample $x$ to approximate matrices and we underline the relationship between their spectra and the BB steplength $x$ basis for $\Omega$ is an orthonormal basis for the subspace $\text{null}(\cdot)$ of (11) is not known and, for our study, we need to focus on a sequence of matrices which during the iterations. First of all, we provide a way to realize such a sequence of (1) matrix $\tilde{V}$ is the orthogonal projection onto the subspace $\mathcal{V} = \text{range}(u)$; the matrix $P$ is the orthogonal projection onto $\mathcal{V}^\perp = \text{range}(u)^\perp = \text{null}(u^T)$;

(b) $V = V^T = V^2$ and $P = P^T = P^2$;

(c) $\text{range}(V) = \text{null}(P) = \mathcal{V}$ and $\text{null}(V) = \text{range}(P) = \mathcal{V}^\perp$;

(d) the spectral decomposition of $V$ is $V = W \left[ \begin{array}{ccc} \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} \\ \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} \\ \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} \end{array} \right] W^T$, where $W = \left[ \tilde{W} \quad w \right]$ is an orthogonal matrix of order $m$, with $\tilde{W} \in \mathbb{R}^{m \times (m-1)}$, $w \in \mathbb{R}^m$; the eigenvalues of $V$ are either 1 or 0; $\text{range}(V) = \text{range}(w)$ is the one-dimensional eigenspace associated to the eigenvalue 1 and $\text{null}(V) = \text{range}(\tilde{W})$ is the eigenspace of dimension $m - 1$ associated to the eigenvalue 0;

(e) $P = W \left[ \begin{array}{ccc} \mathbf{I}_{m-1} & \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} \\ \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} \\ \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} & \mathbf{O}_{m-1,1} \end{array} \right] W^T$ is the spectral decomposition of $P$; the eigenvalues of $P$ are either 1 or 0; $\text{range}(P) = \text{range}(\tilde{W})$ is the eigenspace of dimension $m - 1$ associated to the eigenvalue 1 and $\text{null}(P) = \text{range}(w)$ is the one-dimensional eigenspace associated to the eigenvalue 0;

(f) $P = \tilde{W} \tilde{W}^T$ and $V = \mathcal{A} w^T$, with $\tilde{W}^T \tilde{W} = \mathbf{I}_{m-1}$ and $w^T w = 1$, $w = \frac{u}{\|u\|}$; furthermore $\tilde{W}$ is an orthonormal basis of $\text{range}(P) = \mathcal{V}^\perp = \text{null}(u^T)$.

By using the notation $v^T = \left[ v_T^T \quad v_J^T \right]$ and by applying Lemma 2.1 with $u = v_T$, it is possible to construct the matrix $U^*$ used in the definition of $A^*$. Indeed, if we denote by $P^*$ the orthogonal projection onto $\text{null}(v_T^T)$, thanks to part (f) of Lemma 2.1 there exists a matrix $\tilde{W}^* \in \mathbb{R}^{m \times (m-1)}$ whose columns are an orthonormal basis for $\text{null}(v_T^T)$. Consequently, the matrix $\tilde{U}^* = \left[ \mathbf{O}_{m,1} \quad \tilde{W}^* \frac{1}{\|\tilde{w}\|} \right]$ provides an orthonormal basis for $\Omega^*$, since any $n$-vector $x \in \Omega^*$ can be expressed as $x^T = \left[ x_T^T \quad x_J^T \right]$ with $x_T \in \text{null}(v_T^T)$ and $x_J^* = \mathbf{O}_{n-m,1}$.

In the next subsection we will show that, when a gradient projection method is applied for solving problem (11), the spectrum of $A^*$ plays a crucial role in the analysis of the steplength rules.

2.2. The spectral properties of the BB rules in terms of the approximated restricted Hessian matrices

Of course, at the beginning of the iterative process generated by a gradient projection method, the solution $x^*$ of (11) is not known and, for our study, we need to focus on a sequence of matrices which approximate $A^*$ during the iterations. First of all, we provide a way to realize such a sequence of approximation matrices and we underline the relationship between their spectra and the BB steplength selection rules. To achieve this goal, we consider the set of indices introduced in (8). Also in this case, for the sake of simplicity, we assume that the rows/columns of $A$ and the entries of any vector are reordered so that $I_{k-1}$ is related to the first $m_k = 2I_{k-1}$ indices and $J_{k-1}$ contains the last $n - m_k$ indices.

If we consider the orthogonal projection $P_{k-1}$ onto $\text{null}(v_T^T)$,

$$P_{k-1} = I_{I_{k-1}} - \frac{1}{v_T^T \v_{I_{k-1}} v_{I_{k-1}}} v_T \v_{I_{k-1}},$$

from part (f) of the Lemma 2.1 we have that there exists a $m_k \times (m_k - 1)$ matrix $\tilde{W}_{k-1}$

$$P_{k-1} = \tilde{W}_{k-1} \tilde{W}_{k-1}^T$$

and the $n \times (m_k - 1)$ matrix

$$\hat{U}_{k-1} = \left[ \begin{array}{c} \tilde{W}_{k-1} \\ \mathbf{O}_{n-m_k,m_k-1} \end{array} \right]$$

is an orthonormal basis for the subspace

$$\Omega_{k-1} = \left\{ x \in \mathbb{R}^n : \left[ \mathbf{O}_{n-m_k,m_k} \frac{1}{\|v_T^T\|} I_J_{k-1} \right] x = \mathbf{O}_{n-m_k+1,1} \right\}.$$
Therefore, the symmetric positive definite matrix $\tilde{U}_k^T A \tilde{U}_k$ represents an approximation of the matrix $\tilde{U}$ at the iteration $k - 1$.

Now, by using the notation $g^{(k)} = g(x^{(k)})$, we consider $y^{(k-1)} = g^{(k)} - g^{(k-1)}$ and we introduce the following vector:

$$t^{(k-1)} = g^{(k)} - \psi_k v - (g^{(k-1)} - \psi_{k-1} v) = y^{(k-1)} - (\psi_k - \psi_{k-1}) v,$$

where $\psi_{k-1}$ and $\psi_k$ are approximations, computed the iterations $k - 1$ and $k$, of the equality constraint multiplier $\psi^*$ (see the conditions (12)):

$$\psi_{k-1} = \frac{v^T \tilde{U}_{k-1}^T g_{I_{k-1}}^{(k-1)}}{v^T \tilde{U}_{k-1}^T v_{I_{k-1}}}, \quad \psi_k = \frac{v^T \tilde{U}_{k-1}^T g_{I_{k-1}}^{(k)}}{v^T \tilde{U}_{k-1}^T v_{I_{k-1}}}.$$  

(19)

Note that similar quantities to $t^{(k-1)}$ were considered also in the framework of interior point methods (29).

The vector (18) can be written as $t^{(k-1)} = \begin{bmatrix} t_{I_{k-1}}^{(k-1)} \\ t_{J_{k-1}}^{(k-1)} \end{bmatrix}$ and the following equalities hold:

$$t_{I_{k-1}}^{(k-1)} = P_{k-1} y_{I_{k-1}}^{(k-1)} = \tilde{W}_{k-1} W_{I_{k-1}}^T y_{I_{k-1}}^{(k-1)}.$$  

(20)

The next Lemma is useful to understand the role of $t_{I_{k-1}}^{(k-1)}$ in the definition of the BB steplength rules.

**Lemma 2.2.** Given $s^{(k-1)} = x^{(k)} - x^{(k-1)}$ and $t^{(k-1)}$ as in (18), it holds that

(a) $s^{(k-1)} T v = 0$;

(b) $s_{I_{k-1}}^{(k-1)} T v_{I_{k-1}} = 0$;

(c) $s_{I_{k-1}}^{(k-1)} y_{I_{k-1}}^{(k-1)} = s_{I_{k-1}}^{(k-1)} T t_{I_{k-1}}^{(k-1)} = s_{I_{k-1}}^{(k-1)} T t_{I_{k-1}}^{(k-1)}$.

**Proof.** (a) $s^{(k-1)} T v = 0$ since both $x^{(k-1)}$ and $x^{(k)}$ satisfy the equality constraint.

(b) We show that $s_{I_{k-1}}^{(k-1)} T v_{I_{k-1}} = 0$. Indeed,

$$0 = s^{(k-1)} T v = \sum_{i \in I_{k-1}} s_{I_{k-1}}^{(k-1)} T v_{i} + \sum_{i \in J_{k-1}} s_{I_{k-1}}^{(k-1)} T v_{i} = \sum_{i \in I_{k-1}} s_{I_{k-1}}^{(k-1)} T v_{i},$$

where the last equality holds since $s_{J_{k-1}}^{(k-1)} = O_{n-m_{k-1}}$ from the definition of $J_{k-1}$.

(c) From parts (a), we have that

$$s_{I_{k-1}}^{(k-1)} T t_{I_{k-1}}^{(k-1)} = s^{(k-1)} T \left( y^{(k-1)} - (\psi_k - \psi_{k-1} v) \right) = s^{(k-1)} T y^{(k-1)}$$

(21)

and, since $s_{J_{k-1}}^{(k-1)} = O_{n-m_{k-1}}$, the last equality follows easily. \qed

Lemma 2.2 allows us to state that the classical formulation (4) of the first BB rule provides a steplength depending only on the indices belonging to the set $I_{k-1}$:

$$\alpha_{BB}^{(k)} = \frac{s_{I_{k-1}}^{(k-1)} T s_{I_{k-1}}^{(k-1)}}{s^{(k-1)} T y^{(k-1)}} = \frac{t_{I_{k-1}}^{(k-1)} T s_{I_{k-1}}^{(k-1)}}{s_{I_{k-1}}^{(k-1)} T t_{I_{k-1}}^{(k-1)}}.$$  

(22)

In some sense, the rule $\alpha_{BB}^{(k)}$ decides the steplength by capturing information from the current inactive constraints, discarding the effect of the constraints that remain active in the last two iterations. The
Hence, from (29) and (15) we observe that

$$\alpha_k^{\text{EQ-BB2}} = s^{(k-1)T} t^{(k-1)} I_{k-1}.$$  

(23)

Moreover, from part (c) of Lemma 2.2, (20), (28), (29), (15) and (16) we obtain

$$\alpha_k^{\text{BB1}} \text{ and } \alpha_k^{\text{EQ-BB2}} \text{ give spectral information about the matrix } \tilde{U}_{k-1}^T A \tilde{U}_{k-1}. $$

Theorem 2.1 shows that the reciprocals of $\alpha_k^{\text{BB1}}$ and $\alpha_k^{\text{EQ-BB2}}$ give spectral information about the matrix $\tilde{U}_{k-1}^T A \tilde{U}_{k-1}$.

**Theorem 2.1.** Under the assumption that the matrix $A$ is symmetric and positive definite, we have

$$\lambda_{\min}(\tilde{U}_{k-1}^T A \tilde{U}_{k-1}) \leq 1/\alpha_k^{\text{BB1}} \leq \lambda_{\max}(\tilde{U}_{k-1}^T A \tilde{U}_{k-1})$$

(24)

$$\lambda_{\min}(\tilde{U}_{k-1}^T A \tilde{U}_{k-1}) \leq 1/\alpha_k^{\text{EQ-BB2}} \leq \lambda_{\max}(\tilde{U}_{k-1}^T A \tilde{U}_{k-1}).$$

(25)

**Proof.** In the following, we drop for simplicity the iteration counter $k-1$ from $\mathcal{I}_{k-1}$ and $\mathcal{J}_{k-1}$. In view of the gradient projection iteration (2), we have that the entries of the iterate $x^{(k)}$ are

$$x_i^{(k)} = \begin{cases} x_i^{(k-1)} + \nu_{k-1} (r_i^{(k-1)} - x_i^{(k-1)}) & \text{for } i \in \mathcal{I} \\ x_j^{(k-1)} & \text{for } i \in \mathcal{J} \end{cases}$$

(26)

where $r_i^{(k-1)} = (\Pi_{\mathcal{I}} (x_i^{(k-1)} - \alpha_{k-1} g_i^{(k-1)}))$, $i \in \mathcal{I}$. The vector $s^{(k-1)}$ can be partitioned into two subvectors as follows

$$s^{(k-1)} = \begin{pmatrix} s^{(k-1)}_\mathcal{I} \\ s^{(k-1)}_\mathcal{J} \end{pmatrix} = \begin{pmatrix} \nu_{k-1} (x_i^{(k-1)} - x_i^{(k-1)}) \\ \mathcal{O}_{\mathcal{J},1} \end{pmatrix}.$$ 

(27)

Any entry $g_i^{(k)}$, $i = 1, \ldots, n$, of the gradient $g^{(k)}$ has the following expression:

$$g_i^{(k)} = \sum_{j=1}^n a_{ij} x_j^{(k)} - b_i = \sum_{j \in \mathcal{I}} a_{ij} (x_j^{(k-1)} + \nu_{k-1} (r_j^{(k-1)} - x_j^{(k-1)})) + \sum_{j \in \mathcal{J}} a_{ij} x_j^{(k-1)} - b_i$$

$$= g_i^{(k-1)} + \nu_{k-1} \sum_{j \in \mathcal{I}} a_{ij} (r_j^{(k-1)} - x_j^{(k-1)}).$$

Consequently, from (27), we can write

$$y^{(k-1)} = \begin{pmatrix} y^{(k-1)}_\mathcal{I} \\ y^{(k-1)}_\mathcal{J} \end{pmatrix} = \begin{pmatrix} A_{\mathcal{I},\mathcal{I}} s^{(k-1)}_\mathcal{I} \\ A_{\mathcal{I},\mathcal{J}} s^{(k-1)}_\mathcal{I} \end{pmatrix}. $$

(28)

Furthermore, from part (b) of Lemma 2.2 it follows that

$$P_{k-1} s^{(k-1)} = \left( I_{\mathcal{I}} - \frac{1}{v_{\mathcal{I}}^Tv_{\mathcal{I}}} v_{\mathcal{I}}v_{\mathcal{I}}^T \right) s^{(k-1)} = s^{(k-1)}_\mathcal{I}. $$

(29)

Hence, from (29) and (15) we observe that

$$s^{(k-1)T} s^{(k-1)} = s^{(k-1)T} s^{(k-1)} = s^{(k-1)T} P_{k-1} s^{(k-1)} = \|\tilde{W}_{k-1} s^{(k-1)}\|^2. $$

(30)

Moreover, from part (c) of Lemma 2.2, (20), (28), (29), (15) and (16), we obtain

$$s^{(k-1)T} y^{(k-1)} = s^{(k-1)T} t^{(k-1)} = s^{(k-1)T} P_{k-1} y^{(k-1)} = s^{(k-1)T} P_{k-1} A_{\mathcal{I},\mathcal{I}} s^{(k-1)} = s^{(k-1)T} P_{k-1} A_{\mathcal{I},\mathcal{I}} P_{k-1} s^{(k-1)} $$

$$= s^{(k-1)T} W_{k-1} \tilde{W}_{k-1} A_{\mathcal{I},\mathcal{I}} \tilde{W}_{k-1} \tilde{W}_{k-1} s^{(k-1)}$$

(31)
From \[31\] and \[30\], we conclude that \(1/\alpha_k^{BB1}\) is the Rayleigh quotient of the matrix \(\tilde{U}_{k-1}^T A \tilde{U}_{k-1}\) at the vector \(\tilde{W}_{k-1}^T s_{(k-1)}^T\) and the inequality \[24\] holds. Furthermore, by proceeding as for the equalities \[31\], it is immediate to write

\[
t_I^{(k-1)} = \tilde{W}_{k-1}^T \tilde{U}_{k-1} A \tilde{U}_{k-1} \tilde{W}_{k-1}^T s_{(k-1)}^T.
\]  

(32)

As a consequence, since \(\tilde{W}_{k-1}^T \tilde{W}_{k-1} = I_{m-1}\), we obtain

\[
t_I^{(k-1)} T s_I^{(k-1)} = s_I^{(k-1)} T \tilde{W}_{k-1} (\tilde{U}_{k-1}^T A \tilde{U}_{k-1})^2 \tilde{W}_{k-1}^T s_{(k-1)}^T.
\]  

(33)

Since \(\tilde{U}_{k-1}^T A \tilde{U}_{k-1}\) is a symmetric positive definite matrix, we can introduce the vector

\[
z^{(k-1)} = (\tilde{U}_{k-1}^T A \tilde{U}_{k-1})^{1/2} \tilde{W}_{k-1}^T s_{(k-1)}^T,
\]  

(34)

so that the scalar product in \[33\] can be written as

\[
t_I^{(k-1)} T s_I^{(k-1)} = z^{(k-1)} T \tilde{U}_{k-1}^T A \tilde{U}_{k-1} z^{(k-1)},
\]  

(35)

and \(s^{(k-1)} T y^{(k-1)} = z^{(k-1)} T z^{(k-1)}\); thus, \(1/\alpha_k^{EQ-BB2}\) is the Rayleigh quotient of the matrix \(\tilde{U}_{k-1}^T A \tilde{U}_{k-1}\) at the vector \(z^{(k-1)}\) and the inequality \[25\] holds. □

The modified BB2 rule \[23\] not only exhibits the same spectral properties of the BB1 steplength but it also allows to recover a relationship between the two rules analogous to \[3\] and \[10\], as the next Theorem shows.

**Theorem 2.2.** The steplengths \(\alpha_k^{BB1}\) and \(\alpha_k^{EQ-BB2}\) satisfy \(\alpha_k^{EQ-BB2} \leq \alpha_k^{BB1}\).

**Proof.** From the Cauchy-Schwarz inequality, it follows that

\[
\frac{1}{\alpha_k^{BB1}} = \frac{s^{(k-1)} T y^{(k-1)}}{s^{(k-1)} T s^{(k-1)}} = \frac{s_{I_{k-1}}^{(k-1)} T s_{I_{k-1}}^{(k-1)}}{s_{I_{k-1}}^{(k-1)} T s_{I_{k-1}}^{(k-1)}} \leq \frac{\|s_{I_{k-1}}^{(k-1)}\|}{\|s_{I_{k-1}}^{(k-1)}\|^2} \leq \frac{1}{\alpha_k^{EQ-BB2}}.
\]

The spectral properties described in Theorem 2.1 are useful for relating the steplength to the ability of the gradient projection scheme to annihilate the quantity \(g^{(k-1)}_{I_{k-1}} - \psi_{k-1} v_{I_{k-1}}\), that is a remarkable skill since at the solution \(x^*\) we have \(g_{I^*}(x^*) - \psi^* v_{I^*} = 0\). In order to explain this fact, by supposing \(I_{k-1} = I_k\), we observe that

\[
g^{(k)}_{I_k} - \psi_k v_{I_k} = g^{(k)}_{I_k} - \frac{v_{I_k}^T g^{(k)}_{I_k}}{v_{I_k}^T v_{I_k}} v_{I_k} = P_k g^{(k)}_{I_k}
\]

\[
g^{(k)}_{I_{k-1}} - \psi_{k-1} v_{I_{k-1}} = g^{(k-1)}_{I_{k-1}} - \frac{v_{I_{k-1}}^T g^{(k-1)}_{I_{k-1}}}{v_{I_{k-1}}^T v_{I_{k-1}}} v_{I_{k-1}} = P_{k-1} g^{(k-1)}_{I_{k-1}}
\]

(36)

and we show in Theorem 2.3 how a gradient projection step affects the vector \(P_k g^{(k)}_{I_k}\).

**Theorem 2.3.** Assume that \(I_{k-1} = I_k\) and \(\ell_i < (\Pi_{1}(x^{(k-1)} - \alpha_{k-1} g^{(k-1)}))_i < u_i, i \in I_{k-1}\). The following equalities hold:

\[
P_k g^{(k)}_{I_k} = (I_{mk} - \alpha_{k-1} v_{k-1} P_{k-1} A_{I_{k-1}, I_{k-1}, I_{k-1}} P_{k-1}) P_{k-1} g^{(k-1)}_{I_{k-1}}
\]

(37)
\[ \tilde{W}_k \tilde{W}_k^T g^{(k)} = \tilde{W}_{k-1} \left( I_{m_k-1} - \alpha_{k-1} \nu_{k-1} \tilde{U}_{k-1}^T A \tilde{U}_{k-1} \right) \tilde{W}_{k-1}^T 1 g_{k-1}^{(k-1)} \]  \hspace{1cm} (38)

where \( \tilde{W}_{k-1} \in \mathbb{R}^{m_k \times (m_k-1)} \) and \( \tilde{W}_k \in \mathbb{R}^{m_{k+1} \times (m_k+1)} \) are matrices with orthonormal columns such that \( P_{k-1} = \tilde{W}_{k-1} \tilde{W}_{k-1}^T \) and \( P_k = \tilde{W}_k \tilde{W}_k^T \), respectively.

**Proof.** By using equations (27) and (29) and the hypothesis \( \mathcal{I}_{k-1} = \mathcal{I}_k \), we can write
\[
P_k g^{(k)}_{\mathcal{I}_k} = P_{k-1} \left( \tilde{g}^{(k-1)}_{\mathcal{I}_{k-1}} + A \tilde{x}_{k-1} \tilde{s}^{(k-1)}_{\mathcal{I}_{k-1}} \right) - P_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}} + \nu_{k-1} A \tilde{x}_{k-1} \tilde{s}^{(k-1)}_{\mathcal{I}_{k-1}} P_{k-1} - \tilde{x}^{(k-1)}_{\mathcal{I}_{k-1}},
\]
(39)
where, as before, \( r^{(k-1)} = \left( \Pi_{\mathcal{I}_k} \left( x^{(k-1)} - \alpha_{k-1} \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}} \right) \right) I_{k-1} \). Since \( x^{(k)}_{\mathcal{J}_{k-1}} = \tilde{x}^{(k)}_{\mathcal{J}_{k-1}} \) (from the definition of \( \mathcal{J}_{k-1} \)) and \( \ell_{\mathcal{I}_{k-1}} < r^{(k-1)} < \nu_{\mathcal{I}_{k-1}} \), the vector \( \Pi_{\mathcal{I}_k} \left( x^{(k-1)} - \alpha_{k-1} \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}} \right) \) can be written as
\[
\Pi_{\mathcal{I}_k} \left( x^{(k-1)} - \alpha_{k-1} \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}} \right) = \left( r^{(k-1)} \right) \left( x^{(k-1)} \right) - \alpha_{k-1} \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}} \right),
\]
where, by using by notation \( \tilde{e} = x^{(k)}_{\mathcal{I}_{k-1}} - \alpha_{k-1} \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}} r^{(k-1)} \) solves the following problem
\[
r^{(k-1)} = \arg \min \left\{ r : \nu^{T}_{\mathcal{I}_{k-1}} r = \tilde{e} \right\} \frac{1}{2} \left\| r - \left( x^{(k-1)} - \alpha_{k-1} \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}} \right) \right\|^2.
\]

From the KKT conditions related to the previous problem, the vector \( r^{(k-1)} \) has the following expression
\[
r^{(k-1)} = x^{(k-1)}_{\mathcal{I}_{k-1}} - \alpha_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}} - \frac{v^{(k-1)}_{\mathcal{I}_{k-1}} - \alpha_{k-1} \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}}}{v^{(k-1)}_{\mathcal{I}_{k-1}} - \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}}} v^{(k-1)}_{\mathcal{I}_{k-1}} + \frac{\tilde{e} v^{(k-1)}_{\mathcal{I}_{k-1}}}{v^{(k-1)}_{\mathcal{I}_{k-1}} - \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}}} = \frac{v^{(k-1)}_{\mathcal{I}_{k-1}} - \alpha_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}}}{v^{(k-1)}_{\mathcal{I}_{k-1}} - \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}}} v^{(k-1)}_{\mathcal{I}_{k-1}} + \frac{\tilde{e} v^{(k-1)}_{\mathcal{I}_{k-1}}}{v^{(k-1)}_{\mathcal{I}_{k-1}} - \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}}} = x^{(k-1)}_{\mathcal{I}_{k-1}} - \alpha_{k-1} \nu_{k-1} g^{(k-1)}_{\mathcal{I}_{k-1}}.
\]
From equation (39) and the previous one, the first equality of the thesis is proved. The second one follows easily from the definition of \( \tilde{W}_{k-1} \) and \( \tilde{W}_k \).

Thanks to the assumption \( \mathcal{I}_k = \mathcal{I}_{k-1} \), we have that \( \tilde{W}_{k-1} = \tilde{W}_k \) and, due to the linear independence of their columns, from (38) it follows that
\[
\tilde{W}_k \tilde{W}_k^T g^{(k)}_{\mathcal{I}_k} = \left( I_{m_k-1} - \alpha_{k-1} \nu_{k-1} \tilde{U}_{k-1}^T A \tilde{U}_{k-1} \right) \tilde{W}_{k-1}^T 1 g_{k-1}^{(k-1)},
\]
(40)
If we denote by \( \lambda_1, \ldots, \lambda_{m_k-1} \) and \( \xi_1, \ldots, \xi_{m_k-1} \) the eigenvalues and the associated orthonormal eigenvectors of \( \tilde{U}_{k-1}^T A \tilde{U}_{k-1} \), we may write \( \tilde{W}_k^T g^{(k)}_{\mathcal{I}_k} = \sum_{i=1}^{m_k-1} \gamma_i^{(k)} \xi_i \) and \( \tilde{W}_k^T 1 g_{k-1}^{(k-1)} = \sum_{i=1}^{m_k-1} \gamma_i^{(k-1)} \xi_i \). For the eigencomponents \( \gamma_i^{(k)} \) the following recurrence formula can be easily derived from (40)
\[
\gamma_i^{(k)} = (1 - \alpha_{k-1} \nu_{k-1} \lambda_i) \gamma_i^{(k-1)}, \quad i = 1, \ldots, m_k - 1.
\]
(41)
Formula (41) highlights that if \( \alpha_{k-1} \) is an accurate approximation of the inverse of an eigenvalue of \( \tilde{U}_{k-1}^T A \tilde{U}_{k-1} \), since \( \nu_k \in (0, 1) \), a reduction of \( \left| \gamma_i^{(k)} \right| \) with respect to \( \left| \gamma_i^{(k-1)} \right| \) is obtained. By remembering that \( \tilde{W}_k^T g^{(k)}_{\mathcal{I}_k} (x^*) = 0 \), we conclude that the use of a steplength rule providing good approximations of the inverse of the eigenvalues of \( \tilde{U}_{k-1}^T A \tilde{U}_{k-1} \) can be a fruitful strategy for accelerating gradient projection methods for problem (11). In analogy with the box-constrained case (10), the previous theorems suggest that the modified BB2 rule (23) can be exploited within the adaptive strategy (6) in order to design a
steplength selection that better sweeps the spectrum of the inverse of $\tilde{U}_{k-1}^T A \tilde{U}_{k-1}$ with respect to the original rule \([6]\). The resulting scheme can be written as

$$
\alpha_k^{\text{EQ-VABB}_{\text{min}}} = \begin{cases} 
\min \left\{ \alpha_j^{\text{EQ-BB2}} : j = \max\{1, k-m_a\}, \ldots, k \right\} & \text{if } \frac{\alpha_k^{\text{EQ-BB2}}}{\alpha_k^{\text{min}}} < \tau_k \\
\text{otherwise} \end{cases}
$$

where $m_a$ and $\tau_k$ are defined as in \([6]\). We can guarantee that $1/\alpha_k^{\text{EQ-VABB}_{\text{min}}}$ belongs to the spectrum of $\tilde{U}_{k-1}^T A \tilde{U}_{k-1}$ at any iteration only if $m_a = 0$. Indeed, if $m_a > 0$, inequalities \((25)\) do not hold, in general, for $\alpha_j^{\text{EQ-BB2}}$ with $j = \max\{1, k-m_a\}, \ldots, k-1$. However, small values for $m_a$ are acceptable since the final active set stabilizes at some point of the iterative process.

In the following we will denote by $\alpha_k^{\text{EQ-ABB}_{\text{min}}}$ the version of \((42)\) with $\tau_k = \tau$, $\forall k$, that is the steplength strategy suggested in \([26]\) properly modified to account for the single linear equality constraint and the lower and upper bounds.

**Remark 2.1.** Before concluding this section, we mention how to deal with a slight modification of the feasible set in \([11]\): a single linear inequality constraint instead of a single linear equality one. In case of an inequality constraint, if in two successive iterations the linear constraint is active then the BB2 strategy has to be defined according to \([35]\), otherwise it must be fixed according to \([6]\) which only takes into account the presence of the lower and the upper bounds.

### 2.3. Variable metric gradient projection method

In order to improve the convergence rate of algorithm \([2]\), a very popular technique \([10, 12, 14, 19, 33]\) consists in exploiting a variable metric instead of the standard fixed Euclidean one by introducing the variable metric gradient projection method

$$
d^{(k)} = \Pi_{\Omega} D_k \left( x^{(k)} - \alpha_k D_k^{-1} \nabla f(x^{(k)}) \right) - x^{(k)}, \quad x^{(k+1)} = x^{(k)} + \nu_k d^{(k)},
$$

where $\{D_k\}_{k \in \mathbb{N}}$ is a sequence of symmetric and positive definite matrices with all the eigenvalues belonging to $\left[ \frac{1}{\mu}, \mu \right]$, with $\mu \geq 1$ and $\Pi_{\Omega}$ represents the projection operator onto $\Omega$ with respect to the norm induced by $D_k$:

$$
\Pi_{\Omega} D_k (z) = \arg\min_{x \in \Omega} \frac{1}{2} \|x - z\|^2_{D_k} = \frac{1}{2} (x - z)^T D_k (x - z).
$$

The selection of the sequence $\{D_k\}_{k \in \mathbb{N}}$ usually must aim at two main goals: improving the convergence rate and adding some local information about the problem without introducing significant computational costs. Typically, the definition of proper scaling matrices is strictly related to the problem to handle and, for this reason, their setting criteria will be eventually discussed case by case in the section devoted to the numerical experiments.

Also for the scaled gradient projection method \([43]\), its convergence is ensured for any value of the steplength $\alpha_k$ belonging to a compact set \([11\) Theorem 2.1].

The BB strategies have to be properly modified in order to account for the presence of the variable metric. We start with some considerations about the possibility of considering a fixed metric, but different from the Euclidean one. By supposing $D$ is a symmetric and positive definite matrix, we rewrite \([11]\) by taking into account its following precondioned version

$$
\min_{x \in \mathbb{R}^n} f(x(z)) \equiv \frac{1}{2} z^T D^{-1/2} A D^{-1/2} z - b^T D^{-1/2} z + c \quad \text{subject to } D^{1/2} x \leq z \leq D^{1/2} u, \quad v^T D^{-1/2} z = \nu^T z = e.
$$

In term of $x$-variable, the following equalities can be stated:

$$
\begin{align*}
\mathbf{s}^{(k-1)} &= z^{(k)} - z^{(k-1)} = D^{1/2} \mathbf{s}^{(k-1)}, \\
\mathbf{y}^{(k-1)} &= \nabla f(x(z^{(k)})) - \nabla f(x(z^{(k-1)})) = D^{-1/2} \mathbf{y}^{(k-1)}.
\end{align*}
$$
Furthermore, we observe that $\text{range}(v) = \text{range}(D^{-1/2}v)$, so that the matrix of the orthogonal projection onto $\text{range}(v)$ and the related orthogonal projection onto $\text{null}(v^T)$ do not change. Indeed $\overline{\psi}_{k-1}$ is obtained by considering the scalar $\overline{\psi}$ such that

$$\nabla f(x(z^{(k-1)}))_{\mathcal{I}_{k-1}} - \overline{\psi}g_{\mathcal{I}_{k-1}} = 0,$$

where $\mathcal{I}_{k-1}$ is the set of indices defined in (8). By multiplying both the members for $D^{1/2}I_{\mathcal{I}_{k-1}}^{-1}v_{\mathcal{I}_{k-1}}$, we obtain $\overline{\psi}_{k-1} = \psi_{k-1} = \frac{v^T_{\mathcal{I}_{k-1}}g_{\mathcal{I}_{k-1}}}{v^T_{\mathcal{I}_{k-1}}v_{\mathcal{I}_{k-1}}}$, and, with the same argument, $\overline{\psi}_k = \psi_k = \frac{v^T_{\mathcal{I}_{k-1}}g_{\mathcal{I}_{k-1}}}{v^T_{\mathcal{I}_{k-1}}v_{\mathcal{I}_{k-1}}}$. As a consequence, we obtain

$$\begin{align*}
\bar{t}^{(k-1)} &= \nabla f(x(z^{(k)})) - \psi_k \nabla f(x(z^{(k-1)})) + \psi_{k-1} v = \\
&= D^{-1/2}(y^{(k-1)} - (\psi_k - \psi_{k-1})v) = D^{-1/2}f^{(k-1)},
\end{align*}$$

and the BB rules with respect to the preconditioned problem (44) can be written as

$$\begin{align*}
\alpha_k^{\text{BB1}} &= \frac{s^{(k-1)}T \overline{\psi}_{k-1}}{s^{(k-1)}T y^{(k-1)}} = \frac{s^{(k-1)}T D_k s^{(k-1)}}{s^{(k-1)}T y^{(k-1)}} \\
\alpha_k^{\text{EQ-BB2}} &= \frac{s^{(k-1)}T \overline{g}_{\mathcal{I}_{k-1}}}{s^{(k-1)}T \overline{g}_{\mathcal{I}_{k-1}}} = \frac{s^{(k-1)}T (D_k^{-1})_{\mathcal{I}_{k-1}}}{s^{(k-1)}T (D_k^{-1})_{\mathcal{I}_{k-1}}},
\end{align*}$$

where the definition of $\mathcal{I}_{k-1}$ is independent of the variable $z$ or $x$. If $D$ is diagonal

$$\alpha_k^{\text{EQ-BB2}} = \frac{s^{(k-1)}T \overline{g}_{\mathcal{I}_{k-1}}}{s^{(k-1)}T \overline{g}_{\mathcal{I}_{k-1}}} = \frac{s^{(k-1)}T \overline{g}_{\mathcal{I}_{k-1}}}{s^{(k-1)}T \overline{g}_{\mathcal{I}_{k-1}}}.$$

When we deal with a general variable metric, we can think to precondition problem (11) at every iteration by a symmetric and positive definite diagonal matrix $D_k$. As a consequence, the above rules can be generalized to a variable metric gradient projection method as follows

$$\begin{align*}
\alpha_k^{\text{BB1}} &= \frac{s^{(k-1)}T \overline{\psi}_{k-1}}{s^{(k-1)}T y^{(k-1)}} = \frac{s^{(k-1)}T D_k s^{(k-1)}}{s^{(k-1)}T y^{(k-1)}} \\
\alpha_k^{\text{EQ-BB2}} &= \frac{s^{(k-1)}T \overline{g}_{\mathcal{I}_{k-1}}}{s^{(k-1)}T \overline{g}_{\mathcal{I}_{k-1}}} = \frac{s^{(k-1)}T (D_k^{-1})_{\mathcal{I}_{k-1}}}{s^{(k-1)}T (D_k^{-1})_{\mathcal{I}_{k-1}}},
\end{align*}$$

The strategy (47) is the modified version of the following BB2 strategy

$$\alpha_k^{\text{BB2}} = \frac{s^{(k-1)}T \overline{g}_{(k-1)}}{s^{(k-1)}T \overline{g}_{(k-1)}} = \frac{s^{(k-1)}T y^{(k-1)}}{y^{(k-1)}T D_k^{-1} y^{(k-1)}}$$

which takes into account the presence of the scaling matrix but does not consider the inactive constraints of the feasible region at each iteration. Of course, it is possible to employ (46) and (47) to define an alternating strategy for the selection of the steplength which takes into account both the variable metric and the feasible set in (11) by generalizing (42):

$$\alpha_k^{\text{EQ-ABB}_{\min}} = \begin{cases} 
\min \{ \alpha_k^{\text{EQ-BB2}}, \alpha_k^{\text{BB1}} \} : j = \max \{1, k - m_a, \ldots, k\} & \text{if } \frac{\alpha_k^{\text{EQ-BB2}}}{\alpha_k^{\text{BB1}}} < \tau_k \\
\alpha_k^{\text{BB1}} & \text{otherwise}
\end{cases}$$

where $m_a$ and $\tau_k$ are defined as in (6). If the parameter $\tau_k$ does not vary during the iterations, the corresponding generated steplength will be indicated by $\alpha_k^{\text{EQ-ABB}_{\min}}$. 
Remark 2.2. Another way to infer steplength rules (46) and (47) consists in generalizing equations (3) which define the original BB strategies. Indeed, in the case of variable metric gradient projection method the BB rules satisfy the following generalized secant conditions in the norm induced by the matrix $(D_k)_{I_{k-1},I_{k-1}}$:

$$
\alpha_k^{BB1} = \arg \min_{\alpha \in \mathbb{R}} \| \alpha^{-1} s_{I_{k-1}}^{(k-1)} - (D_k^{-1})_{I_{k-1},I_{k-1}} t_{I_{k-1}}^{(k-1)} \|_{(D_k)_{I_{k-1},I_{k-1}}}
$$

$$
\alpha_k^{BB2} = \arg \min_{\alpha \in \mathbb{R}} \| s_{I_{k-1}}^{(k-1)} - \alpha (D_k^{-1})_{I_{k-1},I_{k-1}} t_{I_{k-1}}^{(k-1)} \|_{(D_k)_{I_{k-1},I_{k-1}}}.
$$

(50)

3. The non-quadratic case

In this section we come back to the original non-quadratic problem (1) and we define the spectral properties of $\alpha_k^{BB1}$ and $\alpha_k^{BB2}$ with respect to the Hessian matrix of the objective function at $x^{(k)}$. The multidimensional variant of Taylor’s theorem [38, Theorem 11.1] allows to write the following equation:

$$
y^{(k-1)} = \nabla f(x^{(k)}) - \nabla f(x^{(k-1)}) = \int_0^1 \nabla^2 f(x^{(k-1)} + ts^{(k-1)}) ds^{(k-1)} dt.
$$

(51)

From (20) and (51) and by recalling that $s_{I_{k-1}}^{(k-1)} = 0$, it holds

$$
t_{I_{k-1}}^{(k-1)} = [P_{k-1} \mathcal{O}_{m_k,n-m_k}] y^{(k-1)} = \int_0^1 P_{k-1} \nabla^2 f(x^{(k-1)} + ts^{(k-1)})_{I_{k-1},I_{k-1}} s_{I_{k-1}}^{(k-1)} ds^{(k-1)} dt
$$

and, from part (c) of Lemma 2.2 and the equality $s_{I_{k-1}}^{(k-1)} = P_{k-1}s_{I_{k-1}}^{(k-1)}$, we have

$$
s_{I_{k-1}}^{(k-1)} = s_{I_{k-1}}^{(k-1)} = \left( \int_0^1 \int_0^1 \nabla^2 f(x^{(k-1)} + ts^{(k-1)})_{I_{k-1},I_{k-1}} ds^{(k-1)} dt \right).
$$

Since $s_{I_{k-1}}^{(k-1)} = \nabla^2 f(x^{(k-1)} + ts^{(k-1)})_{I_{k-1},I_{k-1}}$, from the last equality we can conclude that $1/\alpha_k^{BB1}$ can be interpreted as a Rayleigh quotient relative to the average matrix $\nabla^2 f(x^{(k-1)} + ts^{(k-1)})_{I_{k-1},I_{k-1}}$. To give a similar interpretation for $\alpha_k^{BB2}$, we consider the subspace range($W_{k-1}$) and the linear function $\phi$ defined as

$$
\phi(x_{\tilde{W}}) = z_{\tilde{W}} = W_{k-1}^{T} P_{k-1} \nabla f(x_{I_{k-1}}, x_{J_{k-1}})_{I_{k-1}},
$$

where $x_{\tilde{W}} \in \mathbb{R}^m$ and $x_{I_{k-1}} = W_{k-1} x_{\tilde{W}}$ and $x_{J_{k-1}}$ is fixed at the iteration $k-1$ and $k$. We have $W_{k-1} \phi(x_{\tilde{W}}) = P_{k-1} \nabla f(W_{k-1} x_{\tilde{W}}, x_{J_{k-1}})_{I_{k-1},I_{k-1}}$. We assume that $\nabla f$ is a continuously differentiable function, locally invertible in the intersection of $\Omega_{k-1}$ with a neighborhood of $x^{(k-1)}$ including $x^{(k)}$; we define the inverse function $\phi^{-1}$ as $\phi^{-1}(z_{\tilde{W}}) = x_{\tilde{W}} \iff \phi(x_{\tilde{W}}) = z_{\tilde{W}}$, or equivalently

$$
\phi^{-1}(z_{\tilde{W}}) = x_{\tilde{W}} \iff W_{k-1}^{T} P_{k-1} \nabla f(W_{k-1} x_{\tilde{W}}, x_{J_{k-1}})_{I_{k-1},I_{k-1}} = W_{k-1}^{T} \nabla f(W_{k-1} x_{\tilde{W}}, x_{J_{k-1}})_{I_{k-1},I_{k-1}} = z_{\tilde{W}}.
$$

The Jacobian matrix of $\phi^{-1}$ at $z_{\tilde{W}}$ is $(W_{k-1}^{T} \nabla^2 f(W_{k-1} x_{\tilde{W}}, x_{J_{k-1}})_{I_{k-1},I_{k-1}})^{-1}$, equal to the inverse of $W_{k-1}^{T} \nabla^2 f(x_{I_{k-1}}, x_{J_{k-1}})_{I_{k-1},I_{k-1}} W_{k-1}$. The Jacobian matrix of $\phi^{-1}$ at $z_{\tilde{W}}$ is $(W_{k-1}^{T} \nabla^2 f(W_{k-1} x_{\tilde{W}}, x_{J_{k-1}})_{I_{k-1},I_{k-1}} W_{k-1})^{-1}$.
Setting \( \phi^{-1}(z^{(k-1)}_W) = x^{(k-1)}_W \), with \( x^{(k-1)}_{I_{k-1}} = \tilde{W}_{k-1}x^{(k-1)}_W \) and \( \phi^{-1}(z^{(k)}_W) = x^{(k)}_W \), with \( x^{(k)}_{I_{k-1}} = \tilde{W}_{k-1}x^{(k)}_W \), we can write

\[
x^{(k)}_W - x^{(k-1)}_W = \int_0^1 (\tilde{U}_{k-1}^T \nabla^2 f(x^{(k-1)} + ts^{(k-1)})\tilde{U}_{k-1})^{-1}(z^{(k)}_W - z^{(k-1)}_W)dt.
\]

By multiplying both the members of the previous equality for \( y^{(k-1)}_{I_{k-1}}^T \tilde{W}_{k-1} \), we have

\[
y^{(k-1)}_{I_{k-1}}^T s^{(k-1)}_{I_{k-1}} = y^{(k-1)}_{I_{k-1}}^T \tilde{W}_{k-1} \left( x^{(k)}_W - x^{(k-1)}_W \right)
= y^{(k-1)}_{I_{k-1}}^T \tilde{W}_{k-1} \int_0^1 (\tilde{U}_{k-1}^T \nabla^2 f(x^{(k-1)} + ts^{(k-1)})\tilde{U}_{k-1})^{-1}\tilde{W}_{k-1}^T y^{(k-1)}_{I_{k-1}} dt.
\]

Since \( t_{I_{k-1}}^T t_{I_{k-1}} = y^{(k-1)}_{I_{k-1}}^T \tilde{W}_{k-1} \tilde{W}_{k-1}^T y^{(k-1)}_{I_{k-1}} \), we can conclude that \( \alpha_k^{\text{EQ-BB2}} \) can be interpreted as a Rayleigh quotient relative to the average inverse of the matrix \( \tilde{U}_{k-1}^T \nabla^2 f(x^{(k-1)} + ts^{(k-1)})\tilde{U}_{k-1} \) during the \( k \)-th iteration.

4. Numerical experiments

This section is devoted to evaluate the effects of the BB-like rules, modified when necessary according to the issues of the previous sections, on the gradient projection method (2) and eventually its variable metric variant described in Section 2.3, hereafter denoted by SGP. We considered several optimization problems, both quadratic and non-quadratic.

Before presenting the results, we recall some common features shared by to all the numerical experiments performed: for the GP and the SGP methods, we made the following choices.

- Since the projection onto the set \( \Omega \) can be formulated as a root-finding problem and effectively computed by the secant-like algorithm developed in [18], we employed this method to compute a point satisfying the constraints.
- The parameter \( \nu_k \) has been selected by means of the non-monotone version of the Armijo linesearch proposed in [28]: for given scalars \( 0 < \beta, \delta < 1 \), the parameter \( \nu_k \) is set equal to \( \beta^{i_k} \) and \( i_k \) is the first non-negative integer \( i \) for which

\[
f_{\text{max}} - f(x^{(k)}) + \beta^i d^{(k)} \geq -\delta \beta^i \nabla f(x^{(k)})^T d^{(k)}
\]

where \( f_{\text{max}} \) is the maximum value of the objective function in the last \( M \) iterations. For all the experiments we set \( \beta = 0.4 \), \( \delta = 10^{-4} \) and \( M = 10 \).
- In order to guarantee the boundedness of the steplengths, we have always requested that \( \alpha_k \) belongs to the interval \( [\alpha_{\text{min}}, \alpha_{\text{max}}] = [10^{-10}, 10^6] \).

4.1. Random SLB problems

In this section we consider randomly generated test problems. For the quadratic case we analyze the behaviour of the BB strategies and their modified versions on some toy problems in order to also graphically show the validity of inequalities [24] and [25]. Furthermore, for the non-quadratic case, we perform a study on a set of 162 well-known test problems of both small and large dimensions.

4.1.1. Quadratic case

The aim of this section is both to verify the validity of the modified BB2 steplength rule employed alone or in an alternating scheme and to analyze the distribution of the steplengths generated by the considered rules with respect to the eigenvalues of the sequence of the restricted Hessian matrices obtained during the iterative process. In order to reach these goals we randomly generated quadratic SLB problems where the solution, the vector $v$, the number of active constraints at the solution and the distribution of the eigenvalues of the Hessian matrix of the objective function are prefixed. Table 1 summarizes the main features of the three test problems we considered for the investigation of this section.

We evaluate the behaviour of the gradient projection method (2) fitted with different steplength selection rules: BB1, BB2, EQ-BB2, ABB$_{\text{min}}$, EQ-ABB$_{\text{min}}$ and EQ-VABB$_{\text{min}}$. We recall that ABB$_{\text{min}}$ and EQ-ABB$_{\text{min}}$ stand for the particular cases of (6) and (42) where $\tau_k = \tau$, $\forall k$; in our experiments we set $\tau = 0.7$. On the other hand, for the EQ-VABB$_{\text{min}}$ scheme, we fixed $\tau_1 = 0.7$, $m_a = 2$ and $\zeta = 1.3$.

The following stopping criterion was used to stop the GP method:
\[ \|x^{(k)} - x^{(k-1)}\|_{\infty} \leq 10^{-7}. \]  

Figure 1 shows the behaviour of the inverses of the steplengths generated by means of BB1, BB2 and EQ-BB2 with respect to the eigenvalues of the matrices $\tilde{U}_{k-1}^TA\tilde{U}_{k-1}$ at the $k$-th iteration. Particularly, in the first three rows of Figure 1 at the $k$-th iteration, we plotted 20 eigenvalues of the restricted Hessian matrix $\tilde{U}_{k-1}^TA\tilde{U}_{k-1}$ with linearly spaced indices (always including the maximum and minimum eigenvalues) by black dots and the inverse of the steplength $\alpha_k$ by a red cross. Moreover, the blue lines correspond to the maximum and the minimum eigenvalues of the whole Hessian matrix $A$ and the blue circles denote the 20 eigenvalues of the restricted Hessian matrix at the prefixed solution $x^*$ with the same linearly spaced indices considered for the plot at the single iteration. These plots confirm that the inverses of the steplengths generated by the BB1 and the EQ-BB2 rules satisfy inequalities (24)-(25), while the inverses of the steplengths obtained by applying the non-modified BB2 scheme do not belong to the spectrum of the restricted Hessian matrix at any iteration. The fourth row of Figure 1 shows the decrease of the following relative distance
\[ \frac{|f(x^{(k)}) - f^*|}{|f^*|} \]  

between the objective function values obtained by considering the different BB-like rules in the GP method and $f^*$, namely the objective function value at the solution. The decrease of the objective function towards the minimum is considerably accelerated by employing the EQ-BB2 strategy instead of the BB2 one in the GP algorithm. The alternating steplength selection rules also take advantage of the modified version of the BB2 scheme which accounts for the nature of the problem feasible set.

4.1.2. Non-quadratic case

In this section we analyze the practical efficiency of the considered methods on some non-quadratic SLB test problems.

Based on the technique proposed in [23], the test problems were generated in two possible ways, as follows. Starting from an unconstrained minimization problem with a twice continuously differentiable objective function $\phi(x)$,
\[ \min_{x \in \mathbb{R}^n} \phi(x), \]  

...
Figure 1: Behaviour of gradient projection method equipped with different steplength rules on QP1 (left column), QP2 (middle column), QP3 (right column). Distribution of $\alpha_k$ with respect to the iterations for the BB1 (first row), BB2 (second row), EQ-BB2 (third row) rules; error on $f(x^{(k)})$ for the different rules (fourth row).

for which a local minimum point $x^*$ is known, we generated a constrained problem having one of the following formulations:

$$\min_{x \in \mathbb{R}^n} f(x) = \phi(x) + v^T(x - x^*) + \sum_{i \in L} h_i(x_i) - \sum_{i \in U} h_i(x_i)$$  \hspace{1cm} (56)

subject to $\ell \leq x \leq u, \quad v^T x = c$

or

$$\min_{x \in \mathbb{R}^n} f(x) = \phi(x) + v^T x + \sum_{i \in L} h_i(x_i) - \sum_{i \in U} h_i(x_i)$$  \hspace{1cm} (57)

subject to $\ell \leq x \leq u, \quad v^T x = e, \quad e > 0$
where \( v \in \mathbb{R}^n \), \( e \in \mathbb{R} \), \( L = \{ i \mid x_i^* = \ell_i \} \), \( U = \{ i \mid x_i^* = u_i \} \) and \( h_i : \mathbb{R} \to \mathbb{R}, i \in L \cup U \), are twice continuously differentiable non-decreasing functions. Note that the constrained problems defined by (56) and (57) have the same solution \( x^* \) of the unconstrained problem (55); to this end, the scalar \( e \) in the second formulation must be positive. For our tests we selected some well-known non-quadratic functions \( \phi(x) \), described below.

(i) Trigonometric function [25]:
\[
\phi(x) = \| b - (Av(x) + Bu(x)) \|^2,
\]
where \( v(x) = (\sin(x_1), ..., \sin(x_n))^T \), \( u(x) = (\cos(x_1), ..., \cos(x_n))^T \), and \( A \) and \( B \) are square matrices of order \( n = 500 \) with entries generated as random integers in \((-100, 100)\). Given a vector \( x^* \in \mathbb{R}^n \) with entries randomly generated from a uniform distribution in \((-\pi, \pi)\), the vector \( b \) is defined so that \( \phi(x^*) = 0 \).

(ii) Chained Rosenbrock function [40]:
\[
\phi(x) = \sum_{i=2}^{n} (4\varphi_i(x_{i-1} - x_i^2)^2 - (1 - x_i)^2),
\]
where \( n = 500 \), the values \( \varphi_i \), \( i = 1, \ldots, 50 \), are defined as in [40] Table 1 and \( \varphi_{i+50j} = \varphi_i \), \( i = 1, \ldots, 50 \), \( j = 1, \ldots, 9 \). In this case, a solution of the problem (55) is \( x^* = (1, 1, \ldots, 1)^T \).

(iii) Laplace2 function [24]:
\[
\phi(x) = \frac{1}{2}x^TAx - b^Tx + \frac{1}{4}h^2\sum_i x_i^4,
\]
where \( A \) is a square matrix of order \( n = N^3 \), \( N = 100 \), arising from the discretization of a 3D Laplacian on the unit box by a standard seven-point finite difference formula, \( h = \frac{1}{\sqrt{N}} \) and \( b \) is chosen so that
\[
x_i^* \equiv x(kh, rh, sh) = h^3krss(kh - 1)(rh - 1)(sh - 1)e^{-\frac{1}{2}((kh - d_i)^2 + (rh - d_i)^2 + (sh - d_i)^2)},
\]
where the index \( i \) is associated with the mesh point \( (kh, rh, sh) \), \( k, r, s = 1, \ldots, N \) in a lexicographic ordering. Two different settings for the parameters \( d, d_1, d_2 \) and \( d_3 \) are considered:

a) \( d = 20, d_1 = 2, d_2 = 0.5 \),

b) \( d = 50, d_1 = 0.4, d_2 = 0.7, d_3 = 0.5 \).

We used both the formulations (56) and (57) to build the corresponding constrained versions of test problems (i) and (ii), whereas for test problems (iii) we used the latter form only. In our tests, \( v \) was randomly generated from a uniform distribution in \((0, 1)\) and for each of the functions \( \phi(x) \) the following choices for the functions \( h_i(x) \) were made, as suggested in [24]:

1. \( \beta_i(x_i - x_i^*) \),
2. \( \alpha_i(x_i - x_i^*)^3 + \beta_i(x_i - x_i^*) \),
3. \( \alpha_i(x_i - x_i^*)^7/3 + \beta_i(x_i - x_i^*) \),

where \( \alpha_i \) are random numbers in \((0.001, 0.011)\) and \( \beta_i = 10^{-\eta_i \text{ndeg}} \), with \( \eta_i \) random number in \((0, 1)\) and \( \text{ndeg} = 1, 4, 10 \). In order to retain first-order optimality conditions, the Lagrangian multiplier of the single linear equality constraint must be equal to 1 up to sign (for the case [50]) or to \( \phi(x^*) \) up to sign (for the case [51]), while the Lagrangian multipliers associated to the active constraints are easily assigned equal to the values \( \beta_i \), and, therefore, the parameter \( \text{ndeg} \) allows to control the degeneracy of the problem at \( x^* \). The vectors \( \ell \) and \( u \) were defined in order to have the number of active constraints at the solution equal to a prefixed value \( na \); in particular, we set \( na \approx 0.1 \cdot n, 0.5 \cdot n, 0.9 \cdot n \) and the same number of lower and upper active constraints at \( x^* \). The resulting dataset is composed of 162
4.2. Real-life applications SLB problems

In this section we evaluate the performance of the gradient projection method with both standard and modified BB strategies in solving SLB problems arising from three different real-life applications.

4.2.1. Support Vector Machines

The learning methodology called support vector machines (SVMs) implies to solve a quadratic programming problem. In order to delineate the features of such a problem, we briefly recall the SVMs framework (we refer the reader to [11] for a detailed discussion). If \( D = \{(z_i, y_i), \ i = 1, \ldots, n, \ z_i \in \mathbb{R}^m, \ y_i \in \{-1, 1\}\} \) is a training set of labeled examples, the SVM algorithm performs classification of new examples \( z \in \mathbb{R}^m \) by using a decision function \( F : \mathbb{R}^m \rightarrow \{-1, 1\} \) of the form

\[
F(z) = \text{sign} \left( \sum_{i=1}^{n} x_i^T y_i K(z, z_i) + b^* \right)
\]

where \( K : \mathbb{R}^m \times \mathbb{R}^m \rightarrow \mathbb{R} \) denotes a kernel function and \( x^* = (x_1^*, \ldots, x_n^*)^T \) is the solution of

\[
\begin{align*}
\min f(x) &= \frac{1}{2} x^T A x - \sum_{i=1}^{n} x_i \\
\text{subject to} & \quad 0 \leq x \leq C \sum_{i=1}^{n} y_i x_i = 0.
\end{align*}
\]

Once the vector \( x^* \) is computed, the quantity \( b^* \) in (58) is easily derived. The Hessian matrix \( A \) of (59) has entries \( A_{ij} = y_i y_j K(z_i, z_j), \ i, j = 1, 2, \ldots, n \) and \( C \in \mathbb{R}^n \) is a vector with all entries equal to a positive parameter. For our test problems we consider a Gaussian kernel, namely \( K(z_i, z_j) = e^{-\frac{\|z_i - z_j\|^2}{2\sigma^2}} \),
with $\sigma \in \mathbb{R}$. In order to appreciate the validity of the considerations made in Section 2, we compare the behaviour of gradient projection method (2) by varying the steplength among $\alpha_k^{BB1}$, $\alpha_k^{BB2}$, $\alpha_k^{VABB_{\text{min}}}$, $\alpha_k^{\text{EQ}-BB2}$, $\alpha_k^{\text{EQ}-VABB_{\text{min}}}$ in solving problem (59) for four different datasets with the following features.

- **MNIST1000**: $n = 1000$, $C = 10$, $\sigma = 1800$, $\text{rank}(A) = 1000$;
- **MNIST2000**: $n = 2000$, $C = 10$, $\sigma = 1800$, $\text{rank}(A) = 2000$;
- **ADU**: $n = 1000$, $C = 1$, $\sigma = \sqrt{10}$, $\text{rank}(A) = 985$;
- **WEB**: $n = 1000$, $C = 5$, $\sigma = \sqrt{10}$, $\text{rank}(A) = 736$.

We generated these datasets starting from a learning problems repository, called LIBSVM, available at https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/. We selected some datasets for the binary classification and we set the dimension by ourselves. For the alternating steplength selection rules we adopted $\tau_1 = 0.7$, $m_a = 2$ and $\zeta = 1.3$. Finally, the GP method (2) has been stopped when either the relative distance between two successive iterations was lower than $10^{-8}$ or 1000 iterations have been performed. The initial point for all the considered schemes is the null vector.

Given $f^*$ the smallest value of the objective function among the ones obtained by the different methods at the end of the iterative process, Table 2 shows the number of iterations and the computational time needed by the considered schemes to reduce the relative difference (54) below a certain tolerance $\text{tol}$. In Figure 3, we can appreciate the decrease of the relative error (54), with respect to the computational time, for the four datasets. The results reported in Table 2 and Figure 3 show the effectiveness of employing the modified BB2 selection rule, instead of the original one, also in the alternating scheme. The very poor behaviour which can be observed for the GP algorithm implemented with the standard BB2 strategy is clearly outperformed by the one of the GP method where the steplength is chosen by the EQ-BB2 scheme thanks to its ability of better catching the constraints nature. The benefits gained by employing EQ-BB2
instead of BB2 are clear in terms of both number of iterations and computational time. If a method does not succeed in realizing this goal in the prefixed number of iterations (1000), the corresponding entry of the table is left blank.

Table 2: Number of iterations required by each algorithm to reduce the difference \(\|\hat{\Delta}\|\) below given tolerances for test problem WEB, for the four test problems. The corresponding computational time (average over 20 runs) is also reported.

4.2.2. Fiber orientation distribution reconstruction in diffusion MRI

The aim of this section is to consider the problem of intra-voxel reconstruction of the fiber orientation distribution function (FOD) in each voxel of the white matter of the brain from diffusion MRI data. In [31] the authors clarify that the diffusion signal can be represented as the convolution of a response function with the FOD function and, as a consequence, the estimation of the intra-voxel structure can be shaped through a linear model of the form

\[ b = \Phi x + \eta \] (60)

where \( x \in \mathbb{R}^n \) represents the FOD function, \( b \in \mathbb{R}^m \) is the vector of measurements, \( \Phi \) is the linear measurement operator, and \( \eta \) is the acquisition noise. Since problem (60) is ill-posed, it has been proved [1] to be convenient finding a meaningful solution by means of a reweighted \( \ell_1 \) minimization process which involves at each step the solution of a convex problem of the form

\[
\min_{x \in \mathbb{R}^n} f(x) = \|\Phi x - b\|_2^2
\]

subject to \( x \geq 0, \|W x\|_1 = K \) (61)

where \( W \in \mathbb{R}^{n \times n} \) is a diagonal matrix with positive entries. The weighted \( \ell_1 \)-norm constraint induces sparsity on the solution and the weighting matrix \( W \) forces some anatomical properties of the fiber bundles in neighboring voxels. A complete overview about the properties of \( W \) can be found in [1]. It has been shown in [13] and [8] that the presence of a variable metric in first order methods can
significantly improve the performance of the methods themselves in solving problem (61) if compared with their standard non-scaled versions. For this reason we only report the results obtained by comparing the variable metric gradient projection method SGP with different choices for the steplength parameter. Particularly, we consider the P-BB1 and P-BB2 defined in (46) and (48) respectively, the modified version of P-BB2 fixed in (47), called P-EQ-BB2, and the alternating strategies P-EQ-VABB and P-VABB, which can be obtained by (49) by considering the P-BB2 rule instead of the P-EQ-BB2. For P-EQ-VABB and P-VABB the parameters $m_a, \tau_1$, and $\zeta$ have been chosen equal to 2, 0.5 and 3 respectively. As for the variable metric, the sequence $\{D_k\}_{k \in \mathbb{N}}$ has been selected by mimicking the split gradient-based scaling proposed in [3] for quadratic problems: the scaling matrix has the following form

$$D_k = \text{diag} \left( \max \left( \frac{1}{\mu_k}, \min \left( \mu_k, \frac{x^{(k)} \Phi^T \Phi x^{(k)}}{x^{(k)} \Phi^T \Phi x^{(k)}} \right) \right) \right)^{-1}$$

(62)

where $\mu_k = \sqrt{1 + \frac{10^{11}}{(k + 1)^2}}$. Thanks to the parameter $\mu_k$ we force the sequence $\{D_k\}_{k \in \mathbb{N}}$ to asymptotically approach the identity matrix [14 Lemma 2.3]. This condition ensures the convergence of the sequence of the iterates generated by the SGP scheme to a solution of the problem to minimize as proved in [9 Theorem 3.1].

For the numerical comparison we employed the Phantom dataset, which is available at https://github.com/basp-group/co-dmri and is described in [1]. In particular, for this test problem the parameters $m, n, K$ have the following values: $m = 19200$, $n = 257280$, and $K = 3840$. Given $f^*$ the smallest value of the objective function among the ones reached by the different algorithms after performing 4000 iterations, Table 3 summarizes the number of iterations and the computational time needed by the considered scheme to guarantee that the distance (54) is below certain thresholds $tol$. If this requirement is not satisfied in the
prefixed number of iterations (4000) the corresponding entry of the table is left blank. Figure 4 shows the relative difference \(54\) between the objective function values provided by the different methods and the minimum computed value \(f^*\).

By analyzing the results offered in Table 3 and Figure 4 we can reach analogous conclusions to the ones made for the previous numerical experiments. The modified version of the BB2 rule allows the SGP algorithm to largely improve its behaviour in terms of number of iterations and computational time saved with respect to the performance shown if it is combined with the standard BB2 strategy. Similar considerations can be done by comparing the alternating schemes: the adoption of EQ-BB2 instead of BB2 makes P-EQ-VABB\(_{\min}\) much more effective than P-VABB\(_{\min}\) in finding the solution of the optimization problem studied.

Table 3: Number of iterations and computational time required by each algorithm to reduce the difference \(54\) below given tolerances for problem \(61\). The corresponding computational time is also reported.

4.2.3. Image deblurring with Poisson noise

In order to evaluate the behaviour of the proposed steplength rules for a nonlinear programming problem, we consider the smooth TV regularization of an image \(b\) corrupted by Poisson noise. In a Bayesian framework, an approximation of the original object can be obtained by solving a constrained problem where the objective function is the sum of a discrepancy function, typically depending on the noise type affecting the data, and a regularization term adding \textit{a priori} information; simple constraints, expressing physical requirements, can be considered. In the case of Poisson noise, the discrepancy function measuring the distance from the data \(b\) is the generalized Kullback-Leibler (KL) divergence, having the form

\[
f_0(Ax + c; b) = \sum_{i=1}^{n} b_i \log \frac{b_i}{(Ax + c)_i} + (Ax + c)_i - b_i
\]

where \(A \in \mathbb{R}^{n \times n}\) is a linear operator modeling the distortion due to the image acquisition system and \(c \in \mathbb{R}^n\) is a known positive background radiation constant. A typical assumption for the matrix \(A\) is that it has nonnegative elements and each row and column has at least one positive entry (see \(5\) for the
details about the image deblurring problem in presence of Poisson noise). A widely used edge-preserving regularizer is the discrete smooth Total Variation functional, known also as Hyper-surface regularizer, that for an image of $n = N \times N$ pixels is defined as

$$f_1(x) = \sum_{k,\ell} \sqrt{(x_{k+1,\ell} - x_{k,\ell})^2 + (x_{k,\ell+1} - x_{k,\ell})^2 + \gamma^2} - \gamma$$  \hspace{1cm} (64)$$

where $\gamma$ is a small positive constant and periodic boundary conditions are assumed. In summary, a maximum a posteriori estimate of the original image is a solution of the following nonlinear programming problem

$$\min_{x \in \mathbb{R}^n} f(x) = f_0(Ax + c; b) + \rho f_1(x) \quad \text{subject to} \quad x \geq 0, \sum_{i=1}^{n} x_i = K$$  \hspace{1cm} (65)$$

where $K = \sum_{i=1}^{n} b_i - n \cdot c$ is the flux of the image and $\rho$ is a positive parameter balancing the role of the regularization term and the discrepancy function; the box constraints and the single linear equality constraint express the non-negativity of the pixels and the conservation of the image flux respectively.

In particular we can consider as test problem a $512 \times 512$ object representing a micro-tubulin network inside a cell [38]. In this case, the values of the original object $\varpi$ are in the range $[0, 686]$, whereas those of the blurred and noisy image $b$ are in $[0, 446]$; the background was set equal to 1 and the relative distance between the original object and the blurred noisy data in Euclidean norm is 0.756; $\rho$ was set equal to $4 \cdot 10^{-4}$. The value of $\gamma$ was set equal to $10^{-6} \cdot \max_i \{b_i\}$. A ground-truth solution $x^*$, i.e., an estimate of the real minimum point of the problem (65), is obtained by executing an huge number of iterations of the SGP method in [10]. Indeed, it is well known that the above problem can be efficiently addressed by the gradient projection method equipped with a variable metric (see for example [32, 10, 12]). Mimicking the split gradient-based scaling, as in the previous section, the sequence of scaling matrices $\{D_k\}_{k \in \mathbb{N}}$ can be selected as follows

$$B_k = \text{diag} \left( \max \left( \frac{1}{\mu_k}, \min \left( \mu_k, \frac{x^{(k)}_i}{A^T 1 + \rho V(x^{(k)})} \right) \right) \right)^{-1}$$  \hspace{1cm} (66)$$

where $1$ is a vector with all entries equal to 1, $V(x^{(k)})$ is the positive part of the splitting of $\nabla f_1(x) = V(x) - U(x)$ at $x^{(k)}$ (see [5, Cap. 5]) and $\mu_k = \sqrt{1 + \frac{10^{1/2}}{(k+1)^{1/2}}}$. In Table 4 and Figure 5 we report the behaviour of the scaled gradient projection method combined with the steplength rules P-BB1, P-BB2, P-EQ-BB2, P-VABB$_{\text{min}}$ and P-EQ-VABB$_{\text{min}}$. For the alternating rules, we have the following setting of parameters: $m_n = 2$, $\tau_1 = 0.5$ and $\zeta = 3$. Table 4 shows the number of iterations and the time, in seconds, required by the considered methods to reduce the relative error on the objective function below a fixed threshold $tol$, where, in this case, $f^*$ represents the value of $f$ at the ground-truth $x^*$. We report also the relative reconstruction error (RRE) $\frac{\|x^{(i)} - x^*\|_2}{\|x^*\|_2}$ at the iteration $It$. If one of the approaches is not able to reduce the relative error on the objective function under a certain tolerance in the prefixed maximum number of iterations (1000), Table 4 displays the computational time spent and the RRE achieved after the 1000 iterations performed. We denote the corresponding results by a star. Figure 5 shows the relative error of the objective function and the relative minimization error $\frac{\|x^{(i)} - x^*\|_2}{\|x^*\|_2}$ with respect to the number of iterations and the computational time.

We observe that the rules P-BB2 and P-EQ-BB2 have the same behaviour, very similar to the one of P-BB1; indeed, for this problem, the variable metric (in particular the term $x^{(k)}$ in (66)) hides the effects of the rules that take into account the constraints and, at the same time, the equality constraint plays a minor role, since the assumptions on the matrix $A$ already induce the iterates to satisfy the flux constraint. Nevertheless, when the alternating rule is adopted, the use of P-EQ-BB2 can still improve the performance of SGP, achieving in 38 s. (537 iterations) with P-EQ-VABB$_{\text{min}}$ the value of the objective function obtained with P-VABB$_{\text{min}}$ after 67 s. (1000 iterations).
Table 4: Number of iterations and computational time (average over 10 runs) required to reduce the relative error on the objective function below a prefixed $tol$. The corresponding relative reconstruction error achieved is also reported. The star means that the related result has been reached in the maximum number of iterations (1000).

5. Conclusions

This paper deals with the study of the spectral properties of the well-known Barzilai and Borwein steplength selection rules, often employed to accelerate classical gradient projection methods. In the literature, several works are devoted to explain how, in presence of unconstrained quadratic minimization problems, the steplength generated by the BB strategies are related to the eigenvalues of the symmetric and positive definite Hessian matrix of the objective function. This relation has been identified as the responsible of the goodness of the BB approaches. However the influence of a feasible set on the behaviour of the BB rules has been investigated only very recently [16] in the case of box-constrained strictly convex quadratic optimization problems. Our work represents an extension of the analysis presented in [16] for two main reasons.

• A more complicated feasible region defined by a linear equality constraints together with lower and upper bounds has been investigated. All the results developed in [16] can be seen as a particular case of the ones achieved in this paper.

• A possible interpretation of the BB steplength strategies has been also offered in the more general non-quadratic framework in terms of a proper average matrix depending on the Hessian matrix of the objective function at each iteration.

Thanks to the spectral analysis, a possible redefinition of one of the two BB rules has been suggested in order to take into account not only the second-order information related to the Hessian matrix of the objective function, but also the nature of the constraints. Several numerical experiments, carried out on both quadratic and non-quadratic datasets, showed the effectiveness of this modified BB strategy employed either alone or in an alternating steplength selection scheme.
